INDEX.

Abbey, O. L.—Excessive medication, 234.
Abdomen, penetrating wounds of, 611, 812; diagnosis of wounds of, 719; fatty heart from intra-abdominal pressure, 69; nervous pulsation, 365; surgery of, 597, 704.
Abdominal section, pelvic surgery by, 778.
Abortion, method of inducing, 161.
Abscess of liver, 55, 597, 637; ovarian, 108; perityphlitic, 29; of brain, 118; operations for, 445; ischio-rectal during labor, 20; of spleen, 216; ossifluent, 227; in middle ear, 420; mammary, treatment of, 468; in urethra, 654; cold, 131; treatment of, 723; of liver and lungs, 409.
Abscesses, pelvic, 764.
Absorption of antipyrine, 676.
Académie de Médecine, 439.
Acetophenidine, 616.
Acid, hydrochloric in stomach, 813.
Acids, fatty, in wasting diseases, 87; of stomach, investigation of, 390.
Acne, treatment of, 18, 510.
Acute phthisis, 292; intestinal obstruction, 308; renal disease, blood pressure in, 710; articular rheumatism in nursing infant, 809; iodine poisoning, 812.
Address by Dr. J. M. Da Costa, 497.
Adonis vernalis, 383.
Adulteration, bill against, 447; of food, 485.
Ady, A.—Spontaneous cure of perityphlitic abscess, 29; reduction of thyroid dislocation of the thigh bone, 140; case of radical cure of hernia, 662; appendix vermiformis, 716.
Agitans, paralysis, 521.
Agnew, Prof., celebration in honor of, 481, 497.
Agraphia and Aphasia, 400.
Albuminous periostitis, 59.
Albuminuria from irritating the pneumogastric nerve, 95; intermittent, 369.
Alcohol, 720; destiny of, 362; strychnine, contrast of, 582.
Alcoholic beverages, abuse of, 309; asthenia, massage in, 541.
Algerian climate, 570.
Allochiria, 406.
Amaurosis, induction of premature labor in, 148.
Amblyopia, tobacco, formula for, 584.
American Association of Genito-Urinary Surgeons, 551.
Ammoniacal gases, cholera germs destroyed by, 332.
Ammonium, borate of, 128.
Amputation, triple, 438; for railway injury, 423, 431; quadruple, 660; of leg, 669.
Amylene hydrate, 315, 154, 584.
Anachlorhydric or negative digestions, 393.
Anæmia, pernicious, 434.
Anæsthesia, early, 550.
Anæsthetic alkaloid, another, 385; new, 411.
Anæsthetics, insanity from use of, 31.
Analgesine, 685.
Analysts, need for public, 282.
Anatomy, morbid, of pericæcal inflammation, 1.
Aneurism of auricular artery, 81; multiple of aorta, 240; nervous abdominal pulsation simulating, 365; traumatic, 417; of orbit, 447.
Anomalous features in ovariotomy, 319.
Antifebrin, 584; experience with, 62; in feverish conditions, 341; in hemicrania, 517; in nervous disorders, 569; mixture, 720.
Antineuralgic formula, 654.
Antipyretic, resorcin as, 794.
Antipyrine, 741; in hemoptysis, 191, 352; upon nutrition, 117; in epilepsy, 128; uses for, 254; poisoning with, 367; in p pneumonia, 349; in nocturnal emissions, 41 migraine, 407; in labor, 545; indications of as hæmostatic, 181, 516; absorption and exc of, 676; in chorea, 759; in sea sickness, 81
Antiseptic, naphthol as, 96; iodine as, 154; m ery, 397; acidifield corrosive sublimate an remedy in phthisis, 689; ammunition, 82 stetrics, 783.
Antiseptics, incompatibility of, 825.
Antrum, catarrh of, 344.
Anus, artificial, 273;
Aorta, aneurism of, 240;
Aortic and mitral valves, diseases of, 646.
Aphasia, 113, 115; and agraphia, 400.
Apoplexy, spinal, 523.
Apparatus for removal of pleuritic effusion, 6
Apparitions, warning, 319.
Appendix vermiformis, 716.
Aprosexia, 307.
Aromatic vinegar, 822.
Arsenic in treatment of warts, 189.
Art at home, 452.
Artery, auricular, aneurism of, 81; internal pl aneurism of, 417; axillary, embolism of, 5
Arthritis, rheumatoid, 214.
Arthropathy, new form of, 568.
Articular rheumatism, acute 111; in nursing i 809.
Artificial cow's milk, 317.
Asclepias Syriaca for lumbago, 399.
Ashhurst J., Jr.—Case of successful simulta triple amputation for railway injury, wi marks on the technique of multiple ampu 423.
Asphyxia in cholera, treatment of, 668.
Asphyxiated new-born children, resuscitation
Aspirating the heart, 161.
Asserted antagonism of certain poisons, 851.
Asthenia, alcoholic, massage in, 541.
Asthma, treatment of, 788.
Asymmetry of face, 385.
Ataxia, locomotor, 522.
Athetosis in girl, 751.
Atrophic uterus, sterility due to, 264.
Atrophy of optic nerve following chorea, 67
Atropine, somnambulism caused by, 160.
Aulde, John.—Small Doses; Therapeutic C rations, 838.
Auricle, mastoid periostitis from injury to, 6
Aurium tinnitus, advice wanted for, 349.
Authority of boards of health, 860.
Autopsy on Emperor of Germany, 824.
Axilla after exsection, 198.

Baby, gonorrhœa in a, 372.
Bacillus in syphilis, 785.
Bacteria, self protection against, 26; examina sea air for, 280.
Bacteriology, 512.
Bacteriological water-test, 307.
Bacterio-therapy, 612.
Barnes, W. H—Difficult twin labor, 484.
Bates, Jas.—The sewing-machine and its 360.
Baths in childhood, 87.
Battey vs. Tait, 717.
Beck, A. L.—Prescribing druggists, 449.

Belladonna plaster, poisoning from, 583.
Benjamin, D.—Compound fractures, with compound dislocation of shoulder: complete recovery, 775.
Benzine in making suppositories, 128.
Benzoate of sodium in tonsillitis, 254.
Berlin letter, 672.
Beverages, alcoholic, abuse of, 309.
Bichloride, acid solution of, 583.
Bile, action of calomel upon, 676.
Bilharzia hæmatobia, case of, 88.
Biniodide of mercury in surgery, 572.
Birth, live in child-murder, 88; numerous fractures at, 510; in railway car, 93.
Bitters, influence upon function of stomach, 813.
Black tongue, 477.
Blackmail, attempted, 420.
Blackwell, E. T.—Imperfect preparation for the practice of medicine, 102; submucous and subserous fibroids of the uterus, and bony degeneration of the right ovary. Recession of the intramural tumor during treatment. Death by obstruction of the bowels, from pressure and peritoneal inflammation, 329; first impressions of undeveloped diseases and first treatment, 526.
Blackwood, W. R. D.—Electrolysis versus oöphorectomy, 428.
Bladder, piece of catheter from, 51; removal of foreign bodies from, 86; for irritable, 191; operative surgery of male, 418; what constitutes a stone in, 541; washing out, 576; rupture of, 759.
Blindness, sight restored after, 242.
Blistering, liquid 161.
Blood clot, healing under, 119; in brain, circulation, of, 280; pressure, influence of upon transudation, 610; in ligatured vessels, 708; pressure in acute renal disease, 710.
Boils, nitrate of mercury in, 465.
Boldine, new hypnotic, 646.
Borate of ammonium, 128.
Borofuchsine, a stain for tubercle bacilli, 709.
Bowels, death from obstruction of, 329; chronic obstruction of, 602.
Brain, abscess of, 118; of celebrated men, 127; large, in woman, 160; circulation of blood in, 280; surgery of, 372; operations for abscess of, 445; bullet, wound of, 653.
Breasts, hygiene of, 810.
Bright's disease, acute, in children, 317.
Bringier, J. T.—Prescription for headache, 717.
Bronchitis, treatment of, 540.
Broncho-pneumonia, 173.
Brower, Daniel R.—Paralysis agitans; locomotor ataxia; lateral sclerosis; paraplegia, 521.
Brown-Séquard on cerebral localizations, 731.
Brubaker, A. P.—Dental irritation as a factor in the causation of epilepsy, 67.
Bundy, A. D.—Pertussis and jaundice, 30; useful prescriptions, 185; a correction, 251.
Burn, a bad, 92.
Burns, formula for, 518.
Burt, A. Jr.—Onanism and masturbation, 350.
Byers, J. W.—Diseases of the Southern negro, 734;
Byrd, A. H.—Veratrum viride, 820.

Cachexia in Graves' disease, 788.
Cæsarean section, 584, 758.
Cæsarean section, improved, 787.
Caffeine, 551.
Calculus, vesical, 95.
Calomel upon bile, action of, 676.
Camp, C. F.—Chordee a frequent cause of stricture and chronic gonorrhœa, 29.
Camphor in epilepsy, 420.
Canadansis hydrastis, 608.
Cancer of larynx, 187; of stomach, glands in, 245; vaginal hysterectomy for, 538; recurrence of, 537; climate and distribution of 542; presence of, 575; treatment of, 752; abnormal forms of, 570; uterus, removal of, 689; of stomach, rupturing externally, 812.
Cannabis Indica, uses of, 341.
Carbolized spray in carbuncle, 163.
Carbuncle, treatment of, 163.
Carcinoma, inoculation of, 793.
Carcinoma of cervix, 212, 340.
Carotid internal, rupture of, 64; hemorrhage, treatment of, 224; ligature of, 369.
Caseine, basis for emulsions, 56.
Castration in tubercular disease of testis, 509; as a cure for crime, 511; and development of genital tract, 615; impregnation after, 150.
Cataract operations, cocaine in, 653; treatment of, 713.
Catarrh of antrum, 344.
Catgut suture, 542.
Catheter, aseptic two-way, 338.
Catheterizing the male ureters, 651.
Catheterization of ureters, 714.
Caustic balsam, 821.
Caustic paste, improved, 32.
Cellulitis, pelvic 202.
Cerebral tumor, 126, 536; localization, 373, 731; symptoms in pneumonia of children, 674.
Cervical spina bifida, 20; abortive hypertrophic pachymeningitis, 510.
Cervix in virgin, carcinoma of, 212; laceration of, 489; dilatation, cocaine in, 517.
Chapin, John B.—The forcible feeding of the insane, 500, 503.
Chapped hands, 319.
Charcot on aphasia and agraphia, 400.
Charming away of warts, 453.
Cheerfulness as aid to medicine, 345.
Chemical dyspepsia, diagnosis of, 390.
Chewing and swallowing glass, 61.
Child, newborn, survival of, 794.
Child murder, sign of live birth in, 88; new-born, management of, 631; peculiar anomalies of, 660.
Childhood, baths in, 87.
Children, acute nephritis in, 24; washing out stomach in, 90; resuscitation of asphyxiated, 81; affections of middle ear in, 117; heedless talk before, 120; constipation in, 161; heart disturbances in, 169; ophthalmia in, 175; acute Bright's disease in, 317; incontinence of urine in, 419; feeding of, 582; cerebral symptoms in pneumonia of, 674; empyema in, 699; phthisis in, 750; Creasote in affections of lungs in, 822.
Children's Model Ward, 253; eyes, care of, 371; teeth, management of, 509.
Chinese doctor and his fees, 256.
Chisholm, J. J.—Pterygium completely covering the cornea, 633.
Chloral in labor, death after, 596.
Chloride, of methyl, local refrigeration with, 283; of zinc, cancerous uterus removed by, 689.
Chloroform in neuralgia, 213.
Cholera infantum and weather, 239; germs destroyed by ammoniacal gases, 332; asphyxia, treatment of, 668.
Chorea, treatment of, 19; physostigmin in, 384; optic atrophy following, 678; antipyrine in, 759.

Christian science, 791.
Christian science, 383; fatal effect of, 582.
"Christian scientist" gets off, 860.
Chronic wasting diseases, 87.
Cicatrix of suprapubic lithotomy, 759.
Cigar-making and insanity, 217.
Cincinnati letter, 403.
Circulation of blood in brain, 280; action of green hellebore upon, 410.
Circumcision, ritual, tuberculosis by, 379; Israelite, 567.
Climate, Algerian, 570.
Cocaine in skin diseases, 153; in glaucoma, 370; toxic action of, 384; means of differential diagnosis, 384; in dilatation of cervix, 517; use of, 610; in cataract operations, 653; uses of, 822.
Coccygodynia and pruritus ani, 563.
Coccyx, fracture of, 116.
Cod-liver oil, substitute for, 311.
Cohen, S. Solis—Treatment of fœtid coryza, 43.
Cold, instantaneous, 814.
Colds, treatment of, 540.
Colic from intestinal worms, 495.
Colon, idiopathic dilatation of, 382.
Compulsory vaccination, 453.
Conception, period of, 90.
Confinement, quick getting up after, 286.
Congenital syphilis, 516; causing amyloid disease, 21; torticollis, 383; absence of vagina, 614; knock-knee, 723.
Conjugal question, 92.
Conjunctival affections, molasses in, 689.
Conner, J. J.—The management of the new-born child, 631.
Conservatism in gynecology, 743.
Constipation, glycerine injection for, 160; in children, 161.
Consumption, 291; pulmonary, treatment of, 195; apex expansion *versus* pure air in, 295, 302; and sex, 357; statistics of, 450.
Contagion, possible carrier of, 350.
Contagious diseases, quarantining of school children after, 306.
Contagiousness of phthisis, 777.
Contractions of uterus during pregnancy, 242.
Contusion of eye, 150.
Conviction of Dr. Cross for murder, 126.
Copaiba in infantile leucorrhœa, 595.
Cornea, ulcers of, 64; transplantation of, 368; pterygium covering the, 633.
Coroners, rights and duties and powers of, 268.
Corrosive sublimate, poisoning with, 177; in diphtheria, 244; an antiseptic, 617.
Corson, H.—Quinine: its use and abuse, 555; celebration in honor of, 654.
Cotton-packer, 338.
Cough, winter, syrup of tar in, 368.
Court Bibles and disease germs, 382.
Cramp, writers', relief of, 419.
Crandall, J. B.—Cholera germs destroyed by ammoniacal gases, 332.
Cranium wounds, treatment of, 826.
Cranium, wounds of, 45; penetrating gun-shot wounds of, 418.
Creasote in phthisis, 25, 95, 343, 517, 698; in affections of lungs in children, 822.
Creolin in cystitis, 254.
Cretinism, 621.
Crime, castration a cure for, 511.
Criminals, method of identifying, 616.
Criticism, 121.
Croton water, sanitary condition of, 809.
Croup, membranous, 663.
Curetting the uterus in endometritis, 567.
Currier, J. M.—Large brain in a woman, 160; koumiss and lupulin, 221; early accounts of diphtheria in New England, 483.
Cyanosis, 113; mechanism of, 32.
Cyst, intra-ligamentary, 79; ligamentous, 236; spermatic, of scrotum, 669.
Cystic goitre, treatment of, 243; kidney, evolution of, 665; congenital degeneration, 666.
Cystitis, chronic, prescription for, 225; injection of quinine in, 517.
Cystotomy, successful, 51.
Cytisine in migraine, 369.

Dactylitis, syphilitic, 371.
Dangers of water gas, 512.
Davis, N. S.—Pneumonia, 35.
Davis, S. T.—Removal of the uterine appendages as a remedial measure, 802.
Death by decapitation, mechanism of, 567; from druggist's blunder, 616.
Deaver, J. B.—Nephrectomy for new growths, 772.
Deformities, osteoclasis for correction of, 22; influence of heredity upon, 94; cure of, 395.
Delirium, iodoform, 654.
Dental irritation a cause of epilepsy, 67.
Dentistry practice, tribulation of, 513.
Dentition, intra-uterine, 709.
Dermatology, practical course on, 386.
De Wees, W. B.—The conjugal question, 92; diseases and their treatment in Armenia, 467; amenorrhœa, and its treatment, 841.
Diabetes mellitus, saccharine in, 212.
Diagnosis, differential, of syphilitic ulcers, 242; of intestinal obstruction, 279; differential, cocaine as a means of, 384; of chemical dyspepsia, 390; medical *versus* therapeutic, 531; of cerebral tumor, 536; of wounds of abdomen, 719.
Diaphragm, wound of, 99.
Diarrhœa, putrid, 319; infantile, treatment of, 346; fetid, treatment of, 795.
Dicrotism of the pulse in insufficiency of the aortic valves, 850.
Digestions, negative or anachlorhydric, 393.
Dilatation, idiopathic, of colon, 382; digital, of pylorus, 412; of cervix, cocaine in, 517; ampullar, of tongue, 668.
Dioptric cylinder, value of, 718.
Diphtheria, 255, 532; treatment of, 100, 244, 246, 565; prophylaxis in, 147; therapeutics, 151; corrosive sublimate in, 244; early accounts of, 483; membranous, 663; therapeutics of, 797.
Disease, Graves', cachexia in, 788.
Disease, Pott's, 112; heart, 114; Bright's, in children, 317; heart, strophanthus hispidus in, 371; germs, court Bibles and, 332; so-called Hendon cow, 417; tubercular, of testis, 509; Weil's, 576; disease, fatty acids in chronic wasting, 87; of stomach, 389; in Armenia, 467; undeveloped, first impressions of, 526; of aortic and mitral valve, 646; of heart, treatment of, 657; of Southern negro, 734.
Disinfectant, intestinal, 676.
Dislocation of thigh bone, 140; of knee, 150; of head of femur, 343; of both tibiæ, 723; of shoulder, 775.
Disorders, mental, 767.
Dispensary in Washington, 550.
Displacements of uterus, nervous disturbances from, 675.

Distilled water, 720.
Dizziness from injuries to tympanum, 222.
Doctors as commercial travellers, 224.
Dodge, C. L.—Hystero-epilepsy successfully treated with chloride of gold and sodium, 266; spurious hydrophobia, 286.
Doses, small, plea for, 686.
Drinking, effects of, 316.
Druggists, prescribing, 180, 449; unjustly accused, 190; prerogative, 352.
Drugs, collective investigations in regard to, 26.
Dry mouth, 814.
Duodenum, ulcer of, 478.
Dura mater, lakes of blood in, 572.
Dysentery with gangrene of foot, 307; in Ireland, 408; epidemic, treatment of, 485.
Dysmenorrhœa, salicylate of soda for, 160; formula for, 385, 551; cocaine in, 517.
Dyspepsia, gastro-intestinal, 241; chemical diagnosis of, 390.

Ear disease, prevention of, 779.
Ear complications of scarlet fever, 63; middle, affections in children, 117; internal, primary inflammation of, 308; middle, abscess of, mistaken for toothache, 420; disease, post-nasal syringe cause of, 593.
Early rising and longevity, 709.
Eclampsia, third stage of labor, 167; puerperal, 583.
Eclectic physician, charges against, 225.
Ectocardia, 712.
Ectopia lentis, 437.
Eczema, treatment of, 21, 638; of eyelids, 128; formulæ for, 318.
Edinburgh professors, income of, 550.
EDITORIALS:
Creasote in phthisis, 25.
Washing out the stomach for ileus, 25.
Self-protection against bacteria, 26.
Collective investigations in regard to drugs, 26.
Pericæcal inflammation, 27.
Lanolin and bacteria, 27.
Medical testimony in suits for damages, 57.
Tetanus from use of the stomach-tube, 58.
Sub-pubic lithotomy, 58.
Albuminous periostitis, 59.
Varicose veins in the tongue, 59.
Nutrient enemata, 59.
The physician and the surgeon, 89.
A Frenchman's view of medical education in the United States, 89.
The period of conception, 90.
Washing out the stomach in children, 90.
Ptomaines, 91.
The treatment of sterility, 91.
Healing under blood clot, 119.
Heedless talk before children, 120.
Colored sounds, 120.
Criticism, 121.

ERCILDOWNE.

A Private Medical Hospital for Mental and Nervous Diseases.

Situated at Wissinoming, in the suburbs of Philadelphia, eleven miles from Broad Street Station, on the New York Division of the Pennsylvania Railroad, and within two minutes walk of the station. Commodious in structure, richly furnished, having large, airy rooms, thoroughly ventilated and heated and cheerful sun parlors front and rear. It covers twenty-nine acres of lawn and gardens, and is free from malaria. Each case receives the attention and study given to private practice, and physicians can continue as consultants in cases committed by them.

DETROIT.

How Shall Harmonious Relations be best Promoted between Physicians and Pharmacists.

The *Era* offers a prize of fifty dollars in gold for the best answer to this important and extremely practical question. A goodly number of valuable essays have been already received in response to this offer, and they will be published in the current volume of the *Era*. The prize will remain open to competition to all who are interested in the subject until the first of February, 1888.

As an exponent of the progress of scientific and practical pharmacy the *Era* commends itself to the physician as the natural and necessary supplement to his medical journal or journals.

Physicians will be especially interested in the *Era Collective Investigations*, the object of which is to gather and publish evidence from competent observers throughout the land, on practical questions pertaining to pharmacology and scientific therapeutics.

The subscription of the *Era* is only $1.50 per year. For further information, or sample copy, address the publishers, D. O. HAYNES & CO., Box 583, Detroit, Mich.

THE MORBID ANATOMY OF PERI-CÆCAL INFLAMMATION.*

BY J. H. MUSSER, M. D.,
PHYSICIAN TO PHILADELPHIA HOSPITAL.

Much confusion appears to exist in regard to the nomenclature of the inflammatory affections of the region we are about to consider. It may, therefore, be well to state the meaning of the various terms which will be used in this discussion. By typhlitis we shall understand inflammation of the cæcum; by peri-typhlitis, inflammation of the peritoneum covering the cæcum; by para-typhlitis, inflammation of the connective tissue behind the cæcum. The term typhlitis is often used to include inflammation both of the cæcum and of the appendix. We shall, as suggested by Dr. Fitz, use the term appendicitis for inflammation of the appendix, appendicular peritonitis for inflammation of the appendix and its serous covering, and para-typhlitis for inflammation of the connective tissue around the appendix, or, if you please, peri-cæcal.

It is well to know the relative importance of the inflammatory affections in this portion of the intestinal tract. Typhlitis has been considered by systematic writers to be a frequent affection, and yet it is difficult for pathologists to find records of post-mortems in which this condition has been found. It is true that some writers, especially the Germans, have described cases, particularly of stercoral typhlitis, in which inflammation and ulceration of the mucous membrane of the cæcum, by pressure from fecal impaction, was present. Most of us will, however, agree with Fagge that typhlitis is a good general expression, used for all varieties of inflammation occurring in the right iliac fossa; but that, in the majority of cases, the correct term should be appendicitis. Fagge relates a case in which the patient had all the symptoms of peri-typhlitis, with a tumor in the right iliac fossa. He was recovering from this when an acute affection of the pleura caused his death, and at the post-mortem there was found appendicitis, with ulceration and perforation, and not typhlitis. Dr. Wilkes agrees with Fagge in this view, and they consider that the difference in degree of the inflammation alone accounts for the difference in the symptoms, and that most of the cases are due primarily to inflammation of the appendix. That inflammation may occur in the cæcum, as it may occur in any other portion of the large intestine, no one will deny. But we can say, from the records of Dr. Fitz, that perforation of the cæcum is most rare; for, in a most extensive research, he was able to find but three cases, and these were due to foreign bodies. We shall, therefore, with Fagge, consider that appendicitis is the real affection that occurs in the region we are discussing.

A word with reference to the anatomy. The cæcum normally varies much in position as well as in shape. Treves, in his lectures on the anatomy of the intestinal canal, states that the cæcum is most frequently found, not in the right iliac fossa, but on the

* Address at the meeting of the Philadelphia County Medical Society, Dec. 14, 1887.

psoas muscle itself, or in the pelvis; that the cæcum is entirely surrounded by peritoneum rather than only partially; and, therefore, that behind it there is no areolar tissue such as was described by the older anatomists. He does not believe, moreover, that there is a meso-cæcum.

It is also of importance to note variations in the position of the appendix in the consideration of peri-cæcal inflammation. The usual position, as found by Mr. Treves and by Dr. Fitz, is behind the ileum and its mesentery, with the tip pointing toward the spleen. The second most usual position is behind the cæcum with the tip pointing upward. Long appendices usually take this upward direction. Fitz also refers to its lying on the psoas muscle with or without the tip in the pelvic cavity. There are other variations in position. It may stretch across the pelvis and become adherent to the sigmoid flexure of the colon; and in one instance I have seen the appendix in the inguinal canal, associated with hernia. In another instance it was adherent to a pyosalpinx. The appendix varies in size, in the character of its walls, and in regard to its contents. It may vary in length from one and one-fourth to nine inches. There is a famous specimen in which the appendix was nine inches in length, and lay behind the colon, reaching to the under surface of the liver.

In cases dying from causes not associated with this region, the appendix is often found as a cord-like body, having been the seat of previous inflammation. It may have a dilatation either at its blind extremity or in some portion of its length, especially pouch-like at the mouth. Sometimes the entire canal is dilated and filled with catarrhal products. The character of the contents is of importance. Various articles have been found in the appendix, but chiefly fecal masses. Seeds of various kinds, buttons, bristles, worms, shot, pins and gall-stones have also been found. It is in all probability on account of the presence of these foreign bodies that we have the serious secondary symptoms that arise.

I shall next speak of the morbid anatomy of peri-cæcal inflammation. First, with regard to the manner of making an autopsy in such a case. There is usually an extreme degree of peritonitis, and unless the autopsy is made with great care, it will be impossible to find the seat of the perforation, if one exist, and the exact conditions and relations of the peri-cæcal inflammation. The easiest method is to begin at the first loop of intestine that is reached and from that unravel the intestines, separating with great care the adherent parts. If a source of obstruction is found, tie the bowel on both sides and examine the portion in situ, turning the gut if necessary. Such an examination is absolutely necessary in order to make a thorough study of the part.

Inflammation of the appendix is of a simple catarrhal, or of an ulcerative type. That we have catarrhal inflammation we know from the lessons of morbid anatomy. Clinically, however, it would be impossible to determine the presence of such an inflammation. Catarrhal inflammation with succeeding ulceration, local peritonitis, and, finally, perforation, also occurs. In such cases, the following conditions are generally found after death. On section of the abdominal walls there is found, especially in the right iliac region, an œdematous state of the tissues; not only may there be serous œdema, but there may also be infiltration of pus, due to the burrowing from the primary abscess. The peritoneum, if involved, will exhibit an intense degree of inflammation with the characteristic injection, sometimes general, sometimes limited, and more particularly to the right iliac fossa and the pelvis. Serum will be found in the peritoneal cavity, and in some instances pus; blood is occasionally found. In the more severe forms, especially, large flakes of lymph cover the intestines, the parietal peritoneum, and the abdominal organs. The intestines are also more or less adherent to each other, depending upon the duration and the degree of the inflammation. The location of the abscess, for suppuration is usually circumscribed, depends upon the position of the cæcum. There are three positions in which it is most frequently found—either in the right iliac fossa just above Poupart's ligament, or behind the cæcum, or in the pelvis. In a case which recently came under my observation, the abscess was found in the pelvis, one and one-half inches below the level of the psoas muscle, four inches from the anterior superior spine of the ilium on the right side, and two inches from Poupart's ligament. In another case the abscess was found behind the cæcum in the connective tissue of the right iliac fossa. The size of the abscess varies, sometimes containing only two or three ounces of pus, and in other instances as much as a pint or more has been removed. The walls of the abscess differ according to its position. In the first instance mentioned, the upper wall was made up of the cæcum, the right of the pelvic wall, while posteriorly and on the left it was circumscribed by the

adherent intestine. The walls of the abscess may be made up by the intestines alone. The appendix is always found in the abscess, and has undergone changes varying in degree with the duration and severity of the inflammation. Inflammation and ulceration of the mucous membrane, serous or purulent infiltration of the walls, with perforative ulceration and encysted or localized peritonitis, are discovered. In some instances a portion has sloughed entirely off and cannot be found, having undergone dissolution; in others it is found as a soft mass of necrosed tissue. The perforation varies in size; sometimes it completely surrounds the appendix, or even severs it in two; or it is only large enough to admit a probe, while in other instances it can scarcely be detected. Sometimes two or more perforations are found, and frequently they are covered by recent lymph. The canal of the appendix is very often dilated. We usually find in the canal, near the cæcum, a foreign body; it may, however, be found in the abscess. In the cases detailed by Dr. Fitz, foreign bodies were found in sixty per cent. In other cases their presence or absence could not be positively determined, from haste at the autopsy, from their disintegration, or from their discharge into the bowel, so that the proportion is probably larger than stated. There is one point of importance in reference to the surgery of this region, and that is, that the perforation usually occurs within one and one-half or two inches of the colon. Whatever may be the length of the appendix, the perforation is as a rule found at the point just ndicated.

There are, of course, many cases which do not terminate fatally. Under such circumstances resolution takes place, or the abscess becomes encysted, or the abscess ruptures into some neighboring organ. Dr. Bernardy related a case to me in which rupture occurred in the upper portion of the rectum and also through the abdominal wall at the umbilicus. Dr. Edwards had a case in which fully one and one-half inches of the appendix had sloughed off; the abscess ruptured into the bowel, carrying with it the portion of the appendix and a mass of grape seeds, which were discharged together. The abscess may discharge through the abdominal wall, through the scrotum, into the hip-joint, through the loin or the perineum, or in other directions. Sometimes the pus burrows upward, even as high as and into the pleural cavity. I may say that the bladder is a favorite seat for the rupture of such abscesses.

That cure may take place in cases of perforation of the vermiform appendix, one of my specimens distinctly shows. It was prepared by Dr. William Pepper, and belongs to the museum of the Pennsylvania Hospital. The patient died of another affection. The appendix was cord-like, except in one place, where an old perforation was seen, with organized blood-clot and lymph on the surface.

These are the chief points in regard to the morbid anatomy of peri-cæcal inflammation. In the first place, that peri-cæcal inflammation is due to the inflammation, ulceration, and rupture of the appendix vermiformis, with the secondary formation of an abscess; that the position of the abscess depends entirely upon the position of the appendix; that the further course of the abscess cannot be determined; that in the larger number of cases the inflammation and ulceration are due to the presence of a foreign body occluding the canal—a retention inflammation. The sequence of events appears to be as stated; and while it may appear to be a refinement of terms to differentiate between typhlitis and appendicitis, it is almost necessary in order that a correct and well-defined appreciation of the pathology be determined, so that early and proper treatment may be instituted. Unless such a refinement be made, cases of this kind will be frequently treated as simple typhlitis, whereas in ninety per cent., or perhaps a larger proportion, they are cases of inflammation of the appendix.

DIAGNOSIS OF PERI-CÆCAL INFLAMMATION.*

BY WILLIAM PEPPER, M.D., LL.D.,
PROVOST OF THE UNIVERSITY OF PENNSYLVANIA.

I fear that the remarks I shall make may seem vague and desultory, for it is difficult to compress what is to be said within the very reasonable limit assigned. I am quite willing to accept the terms suggested by Dr. Musser, but I do not think that the term para-typhlitis, as indicating inflammation of the peri-cæcal connective tissue, is likely to gain general usage. It is probable that the term peri-typhlitis will continue to be used to indicate inflammation of the walls of the cæcum and of the neighboring connective tissue. Still, anatomically and for parity of nomenclature, it may be well to recognize para-typhlitis as indicating inflammation of the peri-cæcal connective tissue.

The anatomical points made clear by Dr.

*Address at the meeting of the Philadelphia County Medical Society, Dec. 14, 1887.

Musser are very striking. I would merely add to these one or two facts. In the first place, the appendix presents evidences of disease in a very large number of indifferent autopsies. I remember the report of a series of three hundred autopsies, in which there were signs of disease of the appendix in thirty-three per cent., although in none of these was there a history of typhlitis. We have this little organ, singularly useless physiologically so far as we know, placed in a singularly unfavorable position anatomically, very liable to become impacted, so formed that escape of its contents is very difficult, and very prone to become diseased. We must recognize the fact that the appendix is often diseased when we have no reason to suspect such a condition. I cannot agree, however, that the cæcum also is not often the seat of disease. In a long experience, in which I have paid much attention to these cases, I have collected a number of instances of independent cæcal disease, where the cæcum alone presented lesions, sometimes going on to chronic inflammation, ulceration and perforation. The real condition of things seems to be this: In the first place, there are many cases of mild appendicitis which cannot be recognized during life; in the second place, there are a considerable number of cases of typhlitis where the symptoms are chiefly due to inflammation of the walls of the cæcum and of the peri-cæcal connective tissue, which end in recovery. It is impossible in these cases to determine what proportion has been due to appendicitis. Finally, there are also a good many cases of severe appendicitis resulting in ulceration and perforation, with the formation of circumscribed abscess or of general peritonitis. If we could accept the view that perforation of the appendix, leading to peri-typhlitis or para-typhlitis often resulted in recovery by resolution, it would be a matter of comparative indifference where the lesion was chiefly situated; but do clinical experience and anatomical records justify the view that perforation of the appendix, followed by peri and para-typhlitis, often ends in resolution? It is true, that I have found one specimen, and that others have been placed on record where perforation of the appendix has not been followed by grave results, but do these amount to anything comparable with the great mass of cases where lesions of the appendix have occurred with peritonitis and fatal result unless relieved by operation. It seems to me that we have to recognize that while in typhlitis, peri-typhlitis and para-typhlitis, in all probability appendicitis always exists, yet it is often present in only a very mild degree, and can cause only a small portion of the symptoms. This conception seems necessary to a correct diagnosis of these lesions; it is necessary in guiding our treatment.

There appear, then, to be two classes of cases. In one the affection is more limited to the walls of the cæcum and the peri-cæcal connective tissue, and the appendix is affected to a comparatively slight degree. We have no record as to the frequency of such cases. The record is not to be sought on the post-mortem table, for the large proportion of these cases if properly treated from the beginning end in resolution. I have the records of scores of such cases, the vast majority of which ended in resolution. I think the experience of those I address would give a large number of cases of inflammation in the cæcal region so terminating. So large is the number that I cannot consider that in any large proportion of them did perforation of the appendix occur. As I have seen them, these cases are marked by pain as the initial symptom, not excruciating in character, not associated with evidences of collapse, often accompanied with nausea and vomiting, and with elevation of temperature, which continues to rise until decided fever is present. With these symptoms there is excruciating tenderness in the right iliac fossa, a sense of fulness and induration, not rarely with dorsal decubitus and flexed thigh, with a constipated condition of the bowels possibly preceded by one or two irritative movements during the first day, and with these there is considerable acceleration of the pulse. In proportion as the induration and swelling is early and marked, it has seemed to me that the chances are that the appendix is not seriously involved, but that the affection is chiefly one of inflammation of the walls of the cæcum and of the peri-cæcal connective tissue with exudation, and I have no doubt usually accompanied with considerable fecal impaction of the cæcum.

If absolute rest be insisted upon, if abstinence from food, and absolute avoidance of interference with the state of the bowels be adhered to, if local depletion be employed, if counter-irritation followed by the application of the ice-bag, or warm fomentations be employed, and if the internal use of opium and mercury be begun early, the vast majority of such cases terminate in resolution and complete recovery if the convalescent is properly treated—that is, if these restrictions be insisted upon until the sensibility of the part is entirely removed. I am satisfied that the

well-known tendency to the recurrence of typhlitis is largely dependent upon the management of the convalescence from the primary attack. Such would seem to be the diagnostic marks of this type of case.

On the other hand, we know very well that such cases not rarely go on without resolving, that the induration extends, that the symptoms become aggravated and possibly are such as to indicate suppuration, and that at periods varying from seven to fifteen days, pus formation occurs. Such cases demand operative interference, and are successfully treated by the Parker operation. The existence of pus can often be demonstrated by exploratory puncture with a fine aspirator needle.

There is a second class of cases of an entirely opposite character, with which we are all equally familiar. Here the patient may, apparently, have been in almost perfect health, for perforation of the appendix may occur without any previous symptoms of which the patient had complained. But in these cases there has been a catarrhal appendicitis; the fecal matter which is present in nearly every healthy appendix, is no longer able to circulate and escape, because the outlet is partially closed by the swelling of the mucous membrane; the pent-up secretions and the irritating fecal matter excite more serious inflammation in the walls of the appendix; ulceration is established, and finally perforation occurs, and the symptoms of the attack begin. I have rarely seen a fatal case of disease of the appendix where there was not stenosis of its orifice. I think that, to a large extent, it is this tendency to closure, and the accumulation of the secretions and of fecal matter, that causes the more serious type of inflammation and the occurrence of perforative appendicitis.

The first symptom in these cases is usually intense and excruciating pain, so severe at times as to cause collapse, occasionally so severe as to be followed by death in a few hours. Following this there is the rapid development of the signs of peritonitis. The pulse becomes frequent. There is marked tenderness, not in the iliac region only, but also toward the middle of the abdomen. The belly becomes distended, but there is no induration to be felt; there may even be no fulness in the right ileo-cæcal region. The appendix often lies under the cæcum, and I have frequently percussed these cases with great care without finding any evidence of dulness or of induration. After the occurrence of the initial pain, the fever may not rise very rapidly. There may be only moderate febrile reaction for one, two, or three days, associated with continued, moderate pain, simulating an ordinary catarrhal attack with intestinal colic. For two or three days these cases may be viewed as not being seriously ill, so delusive may be the symptoms after the subsidence of the initial pain. In these cases there is absence of ileo-cæcal infiltration, or induration, or tumor, or prominence, or dulness, on percussion. There is in these cases a less degree of vomiting than in the first class of cases mentioned. The vomiting is often rare, and only induced when the stomach is taxed. The bowels are quiet, but not so obstinately constipated and not so strongly resistant to the action of laxatives as in typhlitis, with more or less impaction of the cæcum. After a time, which varies with the intensity of the attack and the direction which the exuded matter has taken, there appear the symptoms of a rapidly spreading, general peritonitis. The belly becomes greatly distended and tender, the coils of intestine are outlined through the tighly stretched skin. The vomiting becomes frequent, the temperature rises, the pulse grows thready and rapid, and we have the familiar signs of general peritonitis. These cases end fatally, from exhaustion, in from five to ten days.

Here are two groups of cases which seem to me to differ not only in degree, but also to differ in the seat of their lesion and the character of that lesion. I cannot believe that in any great number of cases of the first group there is perforation of the appendix. Yet, unless perforation is present, we have seen that all the other lesions of the appendix may exist without the production of any symptoms. Therefore, I cannot attribute to ordinary appendicitis the symptoms of peri-cæcal inflammation which mark the first group of cases. These symptoms we must assign in chief part to the inflammation of the walls of the cæcum and of the peri-cæcal connective tissue.

It is, therefore, of momentous importance that we should be able to diagnose the sort of case that we have to deal with, and that at the earliest moment. I should say, that in proportion as the tumor, prominence, induration, and dulness are marked, delay is safe, especially if rectal examination—the mention of which I have postponed until the last—does not indicate any fulness on the right side of the roof of the pelvis. If this is present, it indicates an amount of exudation which will end in abscess, and is a strong indication for operation. If digital examination, pushed if necessary to the extent of the introduction of the whole hand, reveals no fulness in the roof of the pelvis, I think

delay for several days is justifiable, and with such treatment as I have indicated, the symptoms will, in the majority of cases, subside; and although the case is fraught with great anxiety, resolution will begin, the symptoms will become milder, and the patient recover, and under proper treatment the part will be restored to absolute health without relapse. Even if frequent relapses occur—and I have seen as many as fifteen or eighteen in the same individual—complete recovery may follow a protracted course of treatment with absolute rest, rigidly restricted diet, constant counter-irritation, and suitable alterative treatment internally.

Of course if, after waiting a few days, there is no evidence of the commencement of resolution; if the fever is sustained, particularly if it assume a hectic type, we know from experience that suppuration will not be long postponed. Exploratory puncture should be made, and operation should follow without delay.

The most important question to be considered is: what is the earliest moment that we can establish the diagnosis? On account of the shortness of the time, I limit myself to the differential diagnosis between the two forms of cæcal inflammation to which I have referred. The initial symptoms give us some indication of the seat and the gravity of the attack. Typhlitis and peri-typhlitis soon offer demonstrable symptoms, but as the appendix is hidden under the intestine, the symptoms of perforated appendicitis are often obscure for two or three days. The most careful palpation may fail to show the slightest fulness. The patient may complain of pain over the cæcum, or over the hypogastrium. External examination does not aid us in the diagnosis. Are there any special features which will help us? I would again refer to the importance of the rectal examination. Early and oft-repeated rectal examination is the most important diagnostic means we possess in this class of affections. Often, on opening the body after death, there is no appearance of peritonitis in the exposed coils of intestine. There is no inflammatory process seen outside of the cæcum, and nothing is found until the cæcum is lifted up, when it is discovered that the inflammation is behind it, and extends downward to the pelvis. Sometimes, on removing a layer of lymph, you disclose the pelvis filled with pus. In such cases, if rectal examination should give a sense of distension of the right side of the pelvic roof, might not a puncture be made with a curved exploring needle introduced through the rectum? This has suggested itself to me, although I have never tried it. In this way we might demonstrate the presence of pus, when it would not be possible to do so through the external abdominal wall.

In many of these cases there has seemed to be an unusual abundance of urine and an increased frequency of urination. I think that the former is associated with the absence of vomiting. In typhlitis and peri-typhlitis there is often so much vomiting that very little liquid is absorbed, and the urine becomes concentrated. I have seen cases of perforation of the appendix where the urine was voided at intervals of an hour or an hour and a half, the total amounting to a large quantity. Again, it has seemed to me that in perforation the pain is more apt to extend to the middle line of the abdomen, and sometimes into the genitals, especially into the right testicle and spermatic cord. The agony of pain which marks the initial lesion, the development of fever, the acceleration of the pulse, the distention of the abdomen, the pain referred to some point in the ileo-cæcal region, the comparative rarity of vomiting, the absence of induration and tumor possibly, the ability to detect fulness or induration in the roof of the pelvis by rectal examination, the frequent micturition with a free supply of urine, the pain possibly radiating in the direction of the genitals, have, I think, been, in the majority of cases, the most marked symptoms. Suppuration occurs in these cases very early, even earlier than in the other group of cases. In one case, in which Dr. Keen operated for me as early as the close of the third day, perhaps the earliest operation on record, a pint of pus was found in the pelvis.

So much for the suggestions that I am able to offer with reference to these important affections. The point to which we should bend our exertions should be to determine the early diagnostic symptoms of these two varieties of cæcal inflammation, to see whether there is a constancy in the description that I have given of the first type of inflammation of the walls of the cæcum, which, under proper treatment, offers a considerable hope of recovery. We should, in particular, strive to point out the indications for operation in the two classes of cases. I would ask if general peritonitis may not be a positive indication for instant operation. It has been asserted that general peritonitis is not a contra-indication to laparotomy under other circumstances. If this is the case, the development of general peritonitis in a case of inflammation of the cæcal region would at once indicate operation; for,

after this develops, death results under medical treatment.

I will not take up the question of the diagnosis of these affections from intussusception and internal strangulation. Although this would be necessary for a comprehensive discussion of the subject, the time at our disposal will not permit it on the present occasion.

TREATMENT OF PERI-CÆCAL INFLAMMATION.*

BY THOMAS G. MORTON, M.D.,
SURGEON TO PENNSYLVANIA HOSPITAL, PHILADELPHIA.

For practical purposes the treatment of peri-cæcal inflammation must be divided into two subdivisions, that of the pre-purulent and that of the post-purulent stage; or, first, before formation of pus or of appendix perforation; and, second, after that event.

The treatment of the pre-purulent, irritative, or simple inflammatory disorders of the cæcum and its surroundings, or appendix, should consist of rest in bed, restriction of diet to nourishing liquids, hot poultices or fomentations frequently replaced upon the parts, perhaps local depletion, and possibly the hypodermatic exhibition of morphia to control pain; whilst the bowels should be kept open and free from accumulation of gas and feces by the administration of salines and enemas—perhaps with the addition of turpentine to the latter.

Those disposed to cavil at the advice just given, I would ask: Shall we keep the bowels in liquid condition, and so best prepared to resist peritonitis, should it occur, whilst at the same time the mere draining of fluid from the intestines and surrounding parts would influence for the better the peri-cæcal inflammation? or shall we paralyze and congest, and inflate the bowels by the old-fashioned "splinting" treatment, and thus becon on peritonitis?

Pain of intense character would often be as much an indication for operative relief as for morphia.

Prompt resolution should take place in cases which are not to go on to the stage of pus formation; and very long continuation of symptoms, or relapses, or recurrences, would be strong indications for surgical interference.

The presence of such tedious recovery, relapse or recurrence would point to the probable presence of conditions exceedingly dangerous to the patient, from liability to general peritonitis or perforation at any time; they further would point, as a rule, to the appendix as the source of irritation and danger. Indeed, in man, that worse than useless appendage must be regarded as the root of most evil in the region under consideration.

To illustrate this point by a single impressive instance, let me quote a case which was reported for me in the Philadelphia *Medical Times* of June 11, 1887. It was that of a woman who, for a long time, had been having mild attacks of abdominal pain, located in the region of the cæcum, which had usually yielded with great promptitude to anodynes. During the course of the last attack of that nature, violent symptoms of perforation and general peritonitis came on. I did not see her until two days after this unfortunate accident; but, though she was then in a most desperate condition, I advised operation as her only chance, and forthwith performed abdominal section. The appendix was found perforated in two places, and violent general purulent peritonitis going on. She died a few hours afterward, but I felt better satisfied that the operation had been performed.

Coming now to our second division, suppose the process to have gone beyond the simple, imflammatory stage, and the presence of pus, even a few drops, to have been diagnosed.

In the great majority of instances, the presence of even a minute amount of pus so near to the peritoneum would be of vastly more risk to the patient than that of abdominal section for its relief. Hence, I should operate whenever the diagnosis of pus had been made—occasionally even without positive diagnosis. But in this paper diagnosis of distinct conditions is presumed, and I am expected simply to outline treatment for those defined conditions; hence, without qualification, I repeat that, pus being present in the region of the cæcum, operation is positively indicated.

Many other risks are to be taken rather than those of purulent peritonitis, for early interference will save most if not nearly all cases from this latter dread complication, while the danger of operation becomes slight compared to that of rampant abdominal inflammation.

Local or general peritonitis supervening in a person who has a history of cæcal trouble, or starting during a first attack, would more than justify operation.

At a later or even perhaps chronic stage of the disorder, all available diagnostic skill

*A paper read at the meeting of the Philadelphia County Medical Society, Dec. 14, 1887.

must be exerted when a peri-cæcal abscess may have pointed in an anomalous situation, and we must ever adhere to the modern surgical rule, always to attack pus at its source, if possible. When the cæcum is normally placed, this is always feasible, if the disease be recognized.

Coming now to speak of actual operative measures, the patient, as a matter of course, must be got into the best possible condition, and surgically clean by the usual methods of attempting these ends. Asepsis should rigidly prevail throughout.

The aspirating needle must never be used, for if it does not find pus we cannot be sure that none is present, whilst its own dangers are not inconsiderable. In these cases it is a poor and especially unsafe diagnostic resource.

The abdominal incision should be lateral, *not* median. For if median, the peritoneal cavity would often be needlessly opened, and the cæcum and appendix cannot well be reached or dealt with through it. But if lateral it can be made of less size, circumscribed abscesses will frequently be found before the peritoneum is reached, and at its base all necessary manipulations can be made upon the cæcum, appendix, and surrounding parts without opening the peritoneal cavity, whilst should the abscess or ulcer have reached that cavity the intestines, etc., can just as well be examined and cleansed through a lateral as a median incision.

Attempts to reach the cæcum by the lateral or subperitoneal incision without opening that membrane, will nearly always be found impossible to carry out, and even should the organ be so reached lesions cannot be properly dealt with at the bottom of such an opening.

The favored or lateral incision should begin at a point an inch above Poupart's ligament and to the outer side of the right linea semilunaris be continued in a vertical direction upward about four inches, and carried down through the parietal muscles until pus, cæcum, or peritoneum encircling that organ be reached. Then the wound can be enlarged, if necessary. If pus be found, wash its containing cavity clean, and get a clear view and careful examination of the cæcum and appendix. The latter is almost always the seat of trouble, and perhaps it would be well to excise it whilst we have the chance in any case, for any cæcal trouble would be likely in time to excite disorder of its appendages. Without a doubt it should be so treated if found inflamed, perforated, or harboring a foreign body. This can best be accomplished by ligating it as close as possible to its cæcal attachment and cutting it off. Cæcal perforations, if found, should be closed by Lembert sutures, whilst ulcers, which may be present, but have not perforated, should by the same means be turned into the bowel lumen. If the general peritoneal cavity has not been involved, the abscess or cæcum or what not in view should be gently curetted, washed out with a one to one thousand bichloride of mercury solution, a large glass or rubber drain introduced, and the abdominal wound closed around it with silk sutures, and a dressing superimposed.

If the peritoneum has become involved and but a short time before the operation, the whole abdominal cavity must be most thoroughly washed out with hot (105° to 110°) distilled water, or one to ten thousand bichloride of mercury solution, and cleansed with sponges, and the foreign body, if that has been the source of trouble, searched for. Should peritonitis be found further advanced, the intestines must be withdrawn, and all adhesions parted with the finger or knife during the process of cleansing and before they are returned to the peritoneal cavity. In the case of general peritonitis a glass drain must be carried to the bottom of the pelvis and kept in working order by means of absorbent cotton ropes acting by capillarity. If a second tube is not used for the superficial or peri-cæcal abscess cavity, the drain going to the pelvis must have perforations as high in it as the level of the cæcum and any surrounding trouble.

If the inflammation should be caused by the presence of a foreign body in the cæcum itself, or by impaction of feces, they must be either excised or urged by prudent force along the bowel. In their operative removal a simple incision, afterward united by Lembert sutures, would answer every purpose.

If portions of the cæcum have sloughed or become gangrenous and the breaches of continuity are too large to approximate with Lembert sutures, without producing dangerous constriction of the gut, we will have to content ourselves with the formation of an artificial anus.

Post-operative treatment would consist in keeping the bowels in a fairly soluble condition, the tube clean, and in meeting threatening peritonitis by active purgation.

These same general principles of treatment will hold even for those rare cases of displacement of the cæcum as into scrotal and other herniæ, its abdominal transposition, etc.; the great question in these cases will be diagnosis.

Typhoid, cæcal, or appendicular inflammation or perforation should likewise receive identical treatment as for the simple inflammatory disorders of that region. This whole subject is still in its infancy, so far as a majority of the profession are concerned, but the child is of almost boundless promise.

I can terminate this going over the field of cæcal inflammatory orders, their pathology, diagnosis, and treatment in no better way than by showing to you the patient whose case was reported to you by Dr. Woodbury, in April last, and upon whom I operated. He has been benefited as much, by the practical application of the principles of treatment which have been laid down, as any human creature ever can be.

DOUBLE OVARIOTOMY; DIVISION OF PEDICLES WITH THERMO-CAUTERY.

BY J. M'F. GASTON, M.D.,

PROFESSOR OF SURGERY IN SOUTHERN MEDICAL COLLEGE, ATLANTA, GA.

It may appear to be a work of supererogation at the present day to present the dealings of surgery with ovarian tumors; but some points of special interest in a case recently under my care may be considered as an excuse for giving the following details:

During the month of October, 1887, I was called to examine a white woman, thirty-six years old, who had been married eighteen years, and has had a son fifteen years ago, and a daughter nine years ago, without any subsequent conception. She was of small stature, and thin, not over ninety pounds in weight when in health, and has led an active indoor life until within the past few months. Her menstrual function has not been interrupted, notwithstanding that an abdominal tumor commenced in the right iliac region about three years ago, and has continued to develop until it completely fills the space from the pelvic bones up to the sternum and ribs. Upon instituting an examination, with the assistance of Dr. W. D. Bizzell, first by palpation externally, and then by the vagina and rectum, a multilocular cystic development, with a limited mass of solid matter, was recognized, without any indication of the attachment. An ovarian tumor was diagnosticated, extending throughout the entire anterior portion of the abdominal cavity, with a protrusion corresponding to that of a woman at full term of pregnancy. It descended into the pelvis, so as to press upon the rectum below the promontory of the sacrum, and rested upon the posterior vaginal wall. With the aid of the uterine sound, the womb was found to be crowded out of its proper position, and lay inclined to the right of the pelvis, with normal depth of cavity.

The general health of the patient not being materially impaired, and the growth of the tumor progressing, the conditions indicated a fair prospect of relief by an operation. It was arranged that laparotomy should be undertaken on the 5th of November, and every preparation was completed for the operation, when a lady friend of the patient stated that she expected the tumor to be removed without extirpating the ovaries. This took us all aback, and I proceeded to explain to her that the tumor was formed by the ovary which must necessarily come away with it; while the other ovary might prove to be also diseased, and in this event might have to be taken away. She had evidently been under some misapprehension as to the exact scope of the operation which was proposed, though I had attempted to convey a correct impression of it previously to her and to her husband. I had them both now to understand, in the presence of some of their lady friends, what was to be done, and that their full and free consent for her to submit to whatever should be thought proper by me and my colleagues, after opening the abdomen, was a prerequisite to entering upon any kind of operative procedure. With the proceedings against Dr. Imlack, of Liverpool, before my mind, I determined not to do anything without their explicit sanction to the extirpation of the ovaries, if this was found to be indicated. Having made all clear to them, and receiving their consent to do whatever was thought by us to be necessary for her relief, I applied sulph. morphia gr. $\frac{1}{4}$ and atropin gr. $\frac{1}{150}$ beneath the skin, and the patient was taken by her husband to the operating table, and put under the anæsthetic influence of the A. C. E. mixture by Drs. G. G. Roy and W. B. Parks. In the meantime the hair was shaved off along the linea alba from the umbilicus to the mons veneris, and the surface washed with soap and water, after which the skin was bathed with a solution of the bichloride of mercury. An alcoholic solution of carbolic acid, having twenty-five per cent. strength, with twice the quantity of water, was used for immersing the instruments, and a weaker dilution employed for soaking the sponges after they had been thoroughly cleansed with hot soap and water. With the co-operation of Drs. J. G. Earnest and W. D. Bizzell in the different

steps of the operation, while Drs. Roy and Parks were entrusted with the responsible duty of watching the effects of the anæsthetic, I proceeded with the laparotomy. An incision six inches in length along the median line, below the umbilicus, was carried down to the peritoneum, when a portion of this membrane was seized with a forceps at the lower end of the external incision, and snipped with scissors, so as to admit a director, upon which the division was made with a narrow bistoury. The opaque sac of one of the cysts presenting was secured with a volsellum and punctured with a large trocar having an elastic tube attached to carry off the fluid contents. Upon being completely evacuated the opening was ligated with strong silk thread and dropped, whereupon other cysts were treated in the same manner, until four were emptied, thus reducing the multilocular tumor until it could be readily brought out at the incision. The pedicle was transfixed by a varicocele needle, armed with a double ligature of No. 14 iron-dyed silk, which was cut in the loop and tied firmly about each portion of tissue, when the ends were cut close to the knot. The outer segment of the pedicle was then divided, an inch from the knot, by Paquelin's thermo-cautery and dropped. While Keith and others have used the actual cautery for searing the cut surface of the pedicle, I am not aware of this process of division of the pedicle by the thermo-cautery being used previously. Upon examining the other ovary it was found to have undergone cystic degeneration, and to have an irregular outline corresponding to the size of a hen's egg, which led us to conclude that it should also be removed. The process of ligation and separation was the same as previously executed, and there was no exudation of blood from either stump; yet some sanguineous effusion from the edges of the external incision had found its way into the cavity, while one of the cysts was so small as not to admit of ligation, and might have allowed a slight escape of the residuary fluid into the peritoneal cavity.

Under these circumstances, it was thought best to wash out the abdomen, and a five per cent. solution of the carbolized alcohol in warm water was poured through the incision, until the cavity was entirely filled. After manipulating the walls of the abdomen so as to cause any foreign matter to become dissolved in the water, the patient was turned upon her side, while the hands prevented any escape of the intestines and the water was discharged, excepting a residue which was soaked up by sponges. The edges of the peritoneal lining were now brought together separately by a continuous catgut suture, and the cavity thus effectually closed. A different course has been pursued by other operators; but, when it is considered that the peritoneum is loosely attached by cellular tissue to the parietes, and is more or less movable in its normal relations, it must appear injudicious to fix it in the linear cicatrix by a deep suture. The skin and fascia were united throughout the entire length of the incision by eleven points of interrupted suture, with No. 12 iron-dyed silk. The line of union was dusted over with iodoform, covered by a thick layer of antiseptic gauze, extending over the entire abdominal region, outside of which was placed some folds of the absorbent cotton, and a broad retention bandage was fastened firmly around the body.

The anæsthetic was now withdrawn, after being kept up for an hour without any untoward developments; and the patient's condition gave no apprehension of shock or other evidence of vital depression. My observation of the safety and efficiency of this combination of one part of alcohol, two parts of chloroform and three parts of ether, known as the A.C.E. mixture, has caused me to use it during the past three years in all surgical operations in preference to chloroform or ether separately. It is not, however, free from the subsequent nausea which attends the long-continued inhalation of anæsthetics, and the patient had some retching during the afternoon; but she was relieved by a mixture of lime water, f℥iij; camphor water, f℥ij; peppermint water, f℥j; in tablespoonful doses every hour.

The night after the operation was passed in comparative comfort, though there was considerable thirst, which was allayed by a limited supply of water and small pieces of ice. The urine was drawn off early next morning, and presented nothing abnormal in its characteristics.

Being unable to pass her urine in the recumbent position the catheter was continued night and morning, there being no indication for more frequent evacuation of the bladder during the first few days. Her bowels were moved by an enema of ox-gall with warm water on the fifth day. The febrile reaction ranged from a temperature of 100° to 102° during the first week, while the pulse counted usually from 110 to 115 per minute. Slight nourishment was taken in moderation after the second day, with a limited amount of water to allay thirst. She took at night a triturate of morphia ¼ grain and atropine

$\frac{1}{150}$ grain, to secure composure, as it was not indicated to relieve pain. Upon renewing the dressing on the fourth day, the incision was united by first intention; and on the seventh day six of the stitches were removed alternately. On the tenth day the remaining five were taken out, without the slightest sign of suppuration at any point. The line of union was again dusted over with iodoform, and the layers of antiseptic gauze were applied fresh, with a new compress of cotton over it, all being well secured by a broad bandage around the body.

In the meantime I allowed her husband to use the catheter in drawing off her urine more frequently, this being called for by her desire to urinate in my absence; and some irritation was set up in the bladder, causing a burning sensation each time after its evacuation, with the presence of some purulent deposition. In view of this vesical trouble, it was determined to dispense with the further use of the catheter; and as she could not pass her water while lying in bed, she was lifted upon the stool, from the end of a week after the performance of laparotomy, as often as three or four times a day, for the relief of the urinary accumulation, and returned afterwards to the bed in the recumbent position.

An interesting phase of this case was the appearance of the menstrual flow on the third day after the operation, and a somewhat free discharge continued for four days, when it gradually disappeared. As she had menstruated during the week preceding the laparotomy, this recurrence was out of time and may perhaps be accounted for by the irritation propagated along the ligated tubes. It was no doubt beneficial as a local derivation from the pelvic traumatism, and the absence of any inflammatory development was probably due in part to this sanguineous discharge at a time when the reaction might have caused trouble on the part of the wounded structures within the abdominal cavity.

The intestinal functions being torpid, enemata of ox-gall with warm water were resorted to repeatedly, at the close of the first week, without producing the desired effect, when the calcined magnesia was used; but failing to act on the bowels, cream of tartar was taken two days in succession, with a recurrence to the enema of warm water having soap and table salt dissolved in it, securing thus a proper evacuation after dislodging some scybala from the intestinal canal.

During this perturbation connected with the bladder and bowels, the temperature dropped rather suddenly, and on the eighth day from the operation was two degrees below normal, with acceleration of the pulse, but on the following day had risen to 97½°, and on the subsequent day returned to the normal standard. This was too late to be attributed to shock from the laparotomy, and was evidently not connected with any septic contamination, so I attributed it to the depressing complication of the disorder of the bladder and intestinal canal, and not to the ovariotomy.

About the end of the second week an anomaly was presented in the secretory function of the mammary glands being developed after its cessation for nearly eight years, and milk was drawn from the breasts continuously during the further observation of the case, which corresponded to the ordinary lactation developed after parturition. We have sufficient grounds for stating that the function of lactation is not interrupted in the inferior animals by spaying, but that a secretion, which had been dormant so long, should be revived by the removal of the ovaries in the human female is a most remarkable feature of this case.

The patient, as already stated, was lifted from her bed after the first week to facilitate the discharges from her bladder and bowels. But after the fifteenth day she rose with some assistance and walked to and from the stool, spending a short time each day in an armed chair; and though her pulse ranged usually from 120 to 130 beats to the minute, her temperature continued normal, and there was no complaint of soreness over the line of incision or in any other portion of the abdomen. There was usually given at night a triturate of sulph. morphia ½ gr. with sulph. atropin $\frac{1}{150}$ gr., under the effect of which she slept during most of the night. As the bowels continued torpid, laxatives followed by enemata were employed at intervals of two or three days.

Upon having their purgative effect, great discomfort and depression of her powers ensued, followed by griping pains in the bowels. Whiskey, alternated with camphor and asafœtida, usually gave relief, accompanied with the external application of camphorated spirits of turpentine. Occasionally there was acute pain extending from the left iliac to the pubic region, with recurrences of the burning sensation after urinating and the continued deposition of more or less pus from the urine, which was voided frequently in small quantity. This was attributed to a complication of cystitis with pyelitis, for which sweet spirits of nitre f℥ss and spirits of turpentine gtt. xv., in mucilage of gum arabic, was given four days in succession,

three times a day, with evident advantage.

While the appetite called for a liberal allowance of nutritive food, and digestion usually progressed satisfactorily, there was at times acidity of the contents of the stomach, for which a half teaspoonful of soda served as a corrective.

As a tonic she was given a mixture of compound tincture of gentian f℥iv and tincture of nux vomica f℥ij, in teaspoonful doses three times a day, with marked improvement in all respects; so that at the end of six weeks after the operation all trouble connected with the bladder and intestinal tract had ceased, and there was no vestige of any inflammatory development connected with the laparotomy. Dec. 18, the patient drove out, and spent the day with a friend, and on the following day I found her entirely well.

EPIDIDYMITIS AND ORCHITIS.

BY J. B. JOHNSON, M.D.,

WASHINGTON, D. C.

Epididymitis and orchitis are most commonly presented as complications of gonorrhœa, and rarely show themselves before the beginning of the second month of a gonorrhœal discharge. As long as the gonorrhœal inflammation is confined to the anterior portion of the urethra, epididymitis and orchitis are exceedingly rare as complications of gonorrhœa; but when a gonorrhœa runs into the second month, the inflammation is apt to gradually extend to the deeper part of the urethra, and from thence, through the vas deferens, to the epididymis. This result is produced in about ten per cent. of the cases of gonorrhœa. Sometimes the inflammation confines itself to the epididymis, and extends no farther; but this is of rare occurrence. The rule is, for the inflammation to extend from the epididymis to the tunica vaginalis, and to the body or substance of the testicle itself, thereby causing acute orchitis. The left testicle is more frequently attacked than the right; but, now and then, both testicles will take on inflammation at the same time, producing double orchitis. When the epididymis and testicle are equally involved in inflammation, it is a difficult matter to distinguish them by the touch; and it is only when the inflammation is not severe, and is not accompanied by an effusion into the tunica vaginalis that it can be ascertained by manipulation that the epididymis is alone concerned in the inflammation. The symptoms are of an active and decided character; and, like those of other local inflammations of a pronounced nature, are too indicative to require an enumeration; and a little inquiry in reference to concomitant symptoms soon invites an easy diagnosis.

The Treatment.—The relief which rest gives to the inflamed epididymis and swelled testicle indicates that the recumbent posture must be constantly maintained in the treatment of inflammation of these organs; and the ease which the lifting the weight of the enlarged and swollen testicle off the tender spermatic cord affords, likewise points out the necessity of keeping the bottom of the scrotum on a level with the top of the thighs, while the recumbent position is steadily maintained. This can be easily accomplished by bringing the testicles to a comfortable height by suitable packing between the thighs. A cloth, frequently wetted with the following lotion, should be constantly applied to the scrotum:

℞ Vinegar,
Water.....āā f℥vij
Tinct. of arnica.....f℥iiss
Powd. muriate of ammonia....℥vj
Mix. Sig.—Shake well, and keep constantly applied to the swelled testicle.

Having enjoined the recumbent position, and placed the testicle in the right position, the next duty is to adopt such internal or constitutional treatment as will be most likely to relieve the epididymis and testicle of their abnormal condition. My plan of treatment has been very satisfactory to me, and has always afforded me speedy and prompt success. The stomach will be found sick, the tongue coated, the skin hot, the pulse quick, and the bowels constipated. I usually order 5 grs. of calomel and 10 grs. of blue mass, made into three pills, at one dose; and in three hours after the pills have been taken, I have administered a half ounce of sulphate of magnesia, and this dose of salts I direct to be taken once a day afterwards, in order to keep the bowels in a soluble condition. It is a well-known therapeutical fact that iodine and its preparations exert a positive effect upon the glandular organs of the body; and in order to avail myself of this physiological action of the iodine preparations, I use the following internally:

℞ Iodide of potassium,
Bromide of potassium.....āā ℥j
Fl'd ext. of aconite root.....gtt. iij
Camphor water..... f℥vj
Mix. Sig.—Shake well. Dose, a tablespoonful every hour.

This dose I have continued every hour until the inflammation begins to diminish, and then

the interval is made every two or three hours, and the medicine continued at these intervals until the swelling and induration of the testicle have entirely disappeared. At the end of from two to four days the orchitis is so much relieved that a suspensory bandage can be worn, and a cautious return to locomotion permitted. Under this treatment the gonorrhœa is very much benefitted, and by the addition of two copaiba capsules, three times a day, the discharge from the urethra rapidly disappears. If the iodide of potash mixture and the copaiba capsules are continued for twelve days after the gonorrhœal discharge has ceased, a cure will be very surely made.

FŒTAL MEDICATION.

BY T. CURTIS SMITH, M. D.,
AURORA, INDIANA.

At first presentation of this thought to the mind, it may seem unreasonable to think of giving remedies to the fœtus in utero. If it includes the idea of direct medication, it certainly would at once be looked upon as an impossibility. But, if we consider the question of dosing the growing intra-uterine inhabitant by an indirect and circuitous route, I think we will find it feasible and practical.

Few medical men need be told that the quality of the mother's blood, her tendencies or her diseases, have great influence over the fœtus *in utero;* any dyscrasia of the mother, any severe disease with which she is suffering is likely to appear in her offspring. The influence of the blood of the mother upon the state of the fœtus is not effected by direct communication, but by a process of osmosis going on in the tissue of the placenta. Cases illustrative of this fact are not wanting. One, which is famous in its way, is that of a French woman who nursed a child with variola while she was pregnant with another; and, when the latter was born, it presented well-marked pustules of small-pox. Sir James Y. Simpson has recorded similar instances in his works on obstetrics. He says: "During the last month I had an opportunity of seeing two cases of variola in the fœtus. Both children were born dead.

"*Case I*.—The first case occured in the practice of Dr. Purdie. The child was near the full time. The variolous eruption was scattered freely over the whole cutaneous surface, in the form of pustules. Several of the pustules were umbilicated. The mother, at the time of the birth of the child, was laboring under an advanced stage of an attack of modified small-pox.

"*Case II*.—In the second case, occurring in the practice of Dr. Gordon, the fœtus was expelled about the fifth month. The pustules were principally confined to the trunk of the fœtus, and consisted chiefly of flattened collections of matter. The mother was recovering from modified small-pox. Intra-uterine small-pox has now been observed by Mead, Jenner, Hosack, and other pathologists.

The fact that the poison of variola can thus produce the disease in infants yet unborn, clearly demonstrates the close connection between the circulation of the mother and that of the fœtus. In one case referred to above, the mother did not herself have the disease, yet her little uterine tenant was born with well-developed variolous pustules. Again, fairly clear evidences of scarlatina and rubeola being conveyed to the fœtus can be adduced were it needful to do so.

An appreciation of the influence of the maternal blood on the condition of the fœtus can be turned to practical account in preventing certain diseased or disordered conditions. In syphilis, for example, medication of the mother is of the greatest service to the fœtus. An illustration of this may be cited from my own practice:

Mrs. X., twenty-six years old, well built, formerly of a sound constitution, had a syphilitic husband, but was unaware of his condition. She had been married six years and had had three abortions. At the time referred to, she had no evidence of uterine disease; but she had enlargement of the post-cervical glands, chronic throat disease, and a distinct history of eruptions. She was very anxious to have a child. I placed her on "specific" treatment for six months, and treated her husband in a similar way. At the end of this time impregnation was allowed to take place, and treatment of the woman was continued nearly to the end of her pregnancy. At the end of her full term she gave birth to a vigorous and apparently healthy infant, which was under my observation for eight years, during which time it appeared healthy to ordinary observation, although the marks of hereditary disease were discoverable by the skilled eye.

Other children were afterwards born to these parents without special treatment, and though they distinctly bore the marks of contamination, they grew up with average vigor and strength.

Again, it is no uncommon occurrence for obstetricians to be called to cases of labor

where there is a "false alarm." This may occur several times in a single case. Not in all, but in a large proportion of such cases, I have found the fœtus in continuous and somewhat violent motion; and I have been led to believe that its intra-uterine gymnastics were the sole cause of the uterine pains. Whenever it stirred forcibly, there would be false labor pains; and whenever it was quiet, there would be none. In the early years of my practice I was kept needlessly at the bedside for many hours in some of these cases. Later, I learned to quiet the fœtus by a pretty round dose of tincture of opium, or of some of its equivalents. In a half hour, or an hour, after giving such a dose, the fœtus would cease its gyrations, and the pains would also cease. I have repeated this practice very many times in twenty-five years' work.

Our obstetric works, I think, take a wrong view of the cause of the false labor pains in this type of these cases. I know there are some cases of simple uterine irritability, where the pains come in advance of time, and need to be quieted by an anodyne or uterine sedative. And also there are cases of malarial uterine neuralgia where quinine or other like salts are needed to allay the regular diurnal or bidiurnal return of false labor pains. But in the type of cases I have described above, the pains are caused by the violent movements of the fœtus, which irritate the uterine walls and lead to contractions and pains.

If clinical experience is worth anything it proves that remedies administered to the pregnant woman produce their effects upon the fœtus through the medium of the blood, which reaches the fœtus by osmotic action. This action is quite free and effectual, and when narcotics are used the result is prompt —so prompt indeed that we should use these agents with care in pregnant women. I have never seen a female morphine-eater bear a living child while under the habit.

Again, a syphilitic woman who is pregnant will increase the chances of the viability of her offspring by persistently using antisyphilitic agents from early in the term to its close; and any dyscrasia of a pregnant woman, if it be likely to affect the fœtus unfavorably, may be met by proper treatment, with a reasonable hope of benefitting both mother and fœtus.

Violent intra-uterine movements may be readily controlled by anodyne or uterine sedative agents.

The administration of any powerful remedy to the mother may cause the death of the fœtus, so that such medicines as opium should be given with great care.

The fœtus may be affected by and even destroyed by the contagium of disease absorbed into the mother's blood, such as variola or scarlatina, though she herself may not have the disease; while, if she be affected with these diseases, the fœtus is liable to die in consequence of her disease.

Any disease which interferes with the normal supply of oxygen in the blood of the pregnant woman will endanger the life of the fœtus: as in pneumonia, bronchitis, typhoid fever, etc.

Diseases which interfere with the normal development of the placenta, endanger the vitality of the fœtus, because it renders the blood-supply to it insufficient.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 14, 1887.

The President, J. Solis-Cohen, M.D., in the Chair.

The meeting was devoted to the subject of

Pericæcal Inflammation.

The discussion on the pathology, diagnosis, and treatment of this disorder was opened by appointment by Dr. J. H. Musser, Dr. William Pepper, and Dr. Thomas G. Morton, whose remarks are published in the preceding pages of this number of the Reporter.

The general discussion was opened by Dr. W. W. Keen, who said: I remember very well the first post-mortem that I made in private practice, twenty-one years ago. It was on a patient who had died of typhlitis without operative treatment, and the question arose in my mind, at that time, whether or not a surgical operation might not have relieved him. This was in the year 1866. In 1867, Willard Parker, of New York, practically systematized the operation. Since then, the sense of the profession in general has been more and more toward the operative treatment of these desperate cases.

I should like to say a word or two with reference to the diagnosis. I have seen many of these cases, and I have yet to see one in which a distinct tumor was present. As a rule, tumefaction will be found, but no tumor. Nor is any fluctuation found in these cases. In a case which I saw in consultation eight years ago, there had been extensive infiltration in the right iliac fossa, for three weeks; but there was absolutely no tumor and no fluctu-

ation; yet, when the cavity was opened, a pint of pus was found. We should make up our minds positively, in reference to the surgical treatment of these cases, that we are not to wait for the formation of a distinct tumor or the presence of distinct fluctuation.

Another symptom, to which Dr. Pepper alluded, I have not found a constant one—and it is surprising that it is not—that is, the flexing of the right thigh. Not only may this be so, but all the other symptoms may be fading, and yet pus be present. In the MEDICAL AND SURGICAL REPORTER, February 6, 1886, p. 165, I reported a case in which I operated on the sixth day. The symptoms had followed the ingestion of a large quantity of grapes, the temperature reaching 102.8°. The fever and pain had nearly disappeared, and the other symptoms had ameliorated to such an extent that convalescence seemed almost established. Here the diagnosis and treatment hinged upon one measure, which I was rather surprised to hear Dr. Morton condemn—that is the use of the aspirator. He, however, did not speak of the hypodermic syringe, and I do not know whether or not he includes that in his condemnation. In these, and certain other cases, I think that the use of the syringe for exploratory purposes is strongly to be commended. I grant that it is not always safe to use the smallest of the needles of the aspirator; but to the use of the hypodermic syringe I see no objection whatever. If it penetrates any normal structure, it will do no harm; and if it reaches pus, it gives a positive indication for operation.

The time at which pus forms is often extremely early. I have had two cases in which on the sixth day a large quantity of pus was found. Both of these cases made excellent recoveries. In the case seen with Dr. Pepper, pus was found as early as the close of the third day.

I was glad to hear Dr. Pepper refer so strongly to the importance of the rectal examination in these cases. Others have alluded to this, but the urgent importance of it has never before been seriously dwelt upon. Dr. Musser has shown that the appendix often lies directly on the brim of the pelvis. If the perforation be near the cæcum, the pus will find its easiest outlet, in not a few cases, toward the cavity of the pelvis. It is, therefore, in the majority of cases, within easy reach of the finger; and, in an urgent case, if it cannot be reached by the finger, the introduction of the hand, provided it be a reasonably small one, may be practiced.

Both Dr. Pepper and Dr. Morton have alluded to operation in these cases. As is well known the operation of Dr. Willard Parker consists of an incision not vertical, but parallel, to Poupart's ligament. This incision will do very well in the majority of cases, where the lesion is situated in the right iliac fossa proper. Either this or the vertical incision to which Dr. Morton alluded, may be selected. As we go further and do not find pus, the hypodermic syringe may be used for purposes of further exploration. In the second class of cases alluded to by Dr. Pepper, where there is perforation of the appendix, where there is absence of induration in the right iliac fossa, and especially if there is general peritonitis, I should certainly favor median and not lateral laparotomy. The latter does not give so simple and bloodless an operation; nor does it give us so easy access to the cavity of the pelvis for exploration, for drainage, and for the surgical manipulations that may be necessary. In the case I operated on one year ago, for Dr. Pepper, I regret that I did not do a median operation at once, instead of doing the lateral operation. The median operation will give us every facility for operation on the viscera in the right iliac fossa, and especially will it give us access to the appendix. Unless the indications for lateral operation be strong, I should favor the median incision.

I should hesitate to perform puncture of the rectum. It would be far better to do a laparotomy, rather than be in the dark, not knowing what the lesion was, and simply drain the cavity of the pelvis, as we would do by rectal puncture. We want to know what condition exists; we want to find out the exact facts. Exploratory operation is not only constantly done, but done, I may almost say, without any additional risk to the patient, and it gives us the means of dealing with whatever lesion we may find. If the appendix is perforated, we should ligate it and remove the diseased portion. If the cæcum should prove to be the seat of perforation, we should close the opening with the Lembert suture. If the perforation is too large for this, it will be necessary to follow the plan suggested by Dr. Morton, and make an artificial anus.

DR. W. HUNT said: The suggestion has been made that treatment with salines should take the place of the opium treatment in these cases, especially after operation. This is a point on which more experience is needed before we can reach a decision. When we take into consideration the fact that several cases of perforation of the appendix have been known to get well under the opium treatment, as proved by post-mortems long

after, and also the fact that the mortality, after the adoption of that treatment years ago, fell to a large extent, we should not hastily abandon it. It is no wonder I feel kindly toward it: for I am told that I am indebted to the opium treatment for my recovery from an analogous lesion,—*i. e.*, perforation of a typhoid fever ulcer.

A word with reference to the operation of ligating and cutting off the appendix. It seems to me that by this method it might possibly be found that only mucous surfaces had been brought into contact and adhesion not secured. It would be better, after removing the diseased portion, to close the stump by the Lembert suture.

Dr. Wm. Osler said: I should like to make one or two remarks bearing upon the anatomy of this region. There can be little or no doubt that the cæcum—namely, that portion of the large intestine below the orifice of the ileum—is, in ninety-five per cent. of all cases, absolutely free. In the one hundred cases analyzed by Treves, there was not one meso-cæcum. If he had examined five or six hundred cases, he might have found two or three. I have the records of many instances in which the cæcum occupied the classical position, and was surrounded by peritoneum only on the front and sides; and last week, in two cases in succession, a well developed meso-cæcum was present.

It is remarkable how large a number of cases of appendix disease recover. I have carefully gone over my notes, and I find six cases of obliteration of the appendix. There had been peri-cæcal inflammation with subsequent obliteration. I find a record of eleven cases of ulceration: seven in phthisis and four in typhoid fever. I have never met with foreign bodies in the appendix; but I have on two occasions had foreign bodies brought to me that had been found in subjects in the dissecting-room.

The important point in connection with perforative appendicitis, is that in the majority of cases the perforation occurs first with slight inflammation in the neighborhood, perhaps lasting a few weeks or months, without exciting any special symptoms; and the first symptoms to which the attention of the physician is called, and which are rapidly followed by peritonitis, are those of perforation, not of the appendix, but of the appendiceal abscess. In five instances of peri-cæcal abscess which I have examined, in every one of them there was evidence that the abscess had lasted some time. That this is the case is evident from the fact that there are many instances—of which I have had three—in which there was no perforation into the peritoneum, and no peritonitis occurred, yet there were signs of septic fever. The perforation had led, not to general peritonitis, but to inflammation of the portal branches and diffuse abscess of the liver. This is a point which, I think, has not been sufficiently recognized in dealing with these cases of perforation of the appendix.

With regard to cæcal disease, we have all seen the cases which have been described by Dr. Pepper. I think that they result, in the majority of instances, from impaction; and that the induration which we feel is in most cases fecal is, I think, evident. As Dr. Pepper has said, it is important to distinguish between these cases and appendicitis, for the majority recover. We, however, learn from post-mortem examinations, that a considerable number of cases of perforation of the appendix also get well—cases, too, in which there have been no special symptoms.

I have had three cases of peri-cæcal abscess from disease of the cæcum. Two were cases of round ulcer of the cæcum. In both the cæcum was the only part involved, the ulcer not being larger than a quarter of a dollar. In both instances the perforation was posterior and had excited suppuration in the tissues as high as the kidney. In one instance the abscess had been opened in the loin and had discharged very freely. In the third case the perforation was due to cancerous ulceration. There was in this case a large perforation just beyond the orifice of the ilium.

Dr. J. C. Wilson said: I should like to indicate a division of the subject which I have not thus far heard mentioned. Dr. Pepper has alluded to the form of inflammation which is so common, and which is probably due to fecal impaction. A large proportion of these cases recover, and the anatomical condition must remain, to a large extent, in doubt. I am disposed to regard it as a local enteritis involving the cæcum, and, perhaps, the appendix. I believe the fulness that is present is due in part to fecal impaction, and in part to plastic exudation around the bowel.

In the second place we have those cases in which there is the formation of peri-cæcal abscess, more or less limited in extent, and in course of time this will require surgical interference.

The third group of cases is that in which there is more or less extensive and general peritonitis; and this peritonitis may be due, as Dr. Osler has pointed out, either to rup-

ture of a peri-cæcal abscess or to primary rupture of the appendix, with the escape of its contents into the peritoneal cavity. I believe that in this form we have to deal with two essentially different processes. In the first place, we have those cases in which we have rapidly developing peritonitis as the result of the escape of the contents of the appendix, or of a peri-cæcal abscess; and these cases demand the surgical interference which has been indicated to-night. I believe that there is another class of these cases in which the peritoneal process results, not in purulent exudation finding its way down into the pelvis, but in plastic exudation from the beginning. Here we have the typical symptoms of general peritonitis without the formation of pus. These cases, I am led to believe from my own experience, not only terminate in recovery, but do better without than with surgical interference.

Dr. J. S. Neff said: The early period at which pus formation takes place in these cases has been referred to. I would only mention a case which illustrates the rapidity with which general peritonitis may appear. I made a post-mortem on a child which was struck with a stone, causing rupture of the bowel. Death occurred seven or eight hours after the accident, not from shock, but from general peritoneal inflammation.

Dr. E. Montgomery said: I have met with a number of cases of these affections. It is certainly difficult to decide what should be our plan of treatment. We have cases in which this trouble exists, and goes on to local peritonitis, and under proper treatment recovery occurs. We have other apparently similar cases which end fatally under the same treatment. Three cases have come under my observation: One was a man some twenty years of age, who complained of severe pain in the right iliac and inguinal region, with considerable tympanites and with symptoms of peritonitis. Leeches, followed by hot poultices, were applied, and morphia administered hypodermically. By the seventh day the acute symptoms began to subside. On the morning of the eighth day he had a severe lancinating pain in the side, with collapse, followed by death a few hours subsequently. The post-mortem revealed gangrene of the end of the appendix. This had been circumscribed by plastic exudation. At the time that the lancinating pain had occurred, an artery had been opened and hemorrhage had occurred, which broke through the exudation, and a pint of blood was found in the peritoneal cavity.

The second case I saw in consultation thirty-six hours before the death of the patient, who was a man fifty years of age. There were marked signs of peritonitis, with great distention of the abdomen, greatly interfering with the breathing. It was not deemed advisable to operate. As there were constant efforts at vomiting, I introduced the stomach tube. This was followed by the regurgitation of half a pint of black material. This gave considerable relief from the distress, and the abdomen was much reduced in size. On post mortem examination, perforation of the appendix was found.

The third case was one of those reported to-night, in which operation was performed.

I have now under treatment a patient seventeen years of age, who, during the last six months, has had eight or ten attacks of tenderness in the right inguinal region. Although he has been in bed for the past three weeks on a restricted diet, he is now suffering from another recurrence of the symptoms. It is a question whether or not in this case it would not be better to do a laparotomy for the purpose of removing the appendix when the inflammation subsides.

Dr. E. T. Bruen said: The treatment of peritoneal inflammation by salines is receiving considerable attention at the present time. From what has been said to-night, it would seem clear that in the treatment of typhlitis the important measures are those which secure rest, including the use of opium and the avoidance of all violence; and when the inflammation has subsided, the removal of the impaction by such mild laxatives as calomel; and, besides this, the treatment of the catarrhal condition by appropriate measures.

In those cases where there has been rupture of the appendix, with the occurrence of peritonitis, it seems improbable that the administration of repeated doses of salines would be likely to do much good. I think that the expression of medical opinion as to the measures to be employed under these circumstances should be clear.

Dr. J. H. Packard said: I would briefly refer to one or two of a number of cases illustrating the subject of this evening's discussion, which have fallen under my observation.

The first occurred in the practice of the late Dr. J. F. Meigs, in 1860, and is reported in detail in the *American Journal of the Medical Sciences* for 1861. At the autopsy, made by me, an intestinal concretion had been lodged in the appendix vermiformis, and had caused a circular band of ulceration, at one point of which perforation had taken place. There was a collection of pus about

the appendix, and universal suppurative peritonis, with flakes of lymph on the coils of intestine.

Another case, which occurred in 1879, in my wards at the Episcopal Hospital, may illustrate the difficulty of diagnosis sometimes met with in these cases before the recent advances in the surgery of this region had been made. A boy, about seventeen years of age, who had worked on a farm, was admitted on account of lameness, ascribed by him to ulceration of his right heel by a heavy and ill-fitting shoe. There was a swelling in the upper part of the thigh, which was regarded as a sympathetic bubo. At the lower part of the abdomen there was also some fulness and tenderness, which should have attracted more attention than it did, and which ought to have suggested the true nature of the case. Several openings occurred below Poupart's ligament; the discharge was very abundant, and soon became fecal in character. A little later, fluctuation was noted above the ligament. Parker's operation was performed, and a small angular piece of beef-bone was found that had worked its way out of the bowel. A more radical procedure, such as would now be resorted to, might have saved the life of this patient, who died exhausted.

As to the employment of the hypodermic syringe for diagnostic purposes, it seems to me that if fluctuation is clear enough to warrant this, its aid is scarcely needed. It must not be forgotten that there are on record several cases in which fatal fecal extravasation has followed the puncture by this means of a herniated bowel.

With regard to the choice between the lateral and median incisions, I think that where the trouble is clearly in the right side of the abdomen, this is the proper surgical entrance. If there is no necessity for opening the peritoneum, it is certainly sufficient. And if there is such necessity, a lateral incision eight inches in length, such as is recommended for other purposes by several surgical writers, will give abundant access.

I would suggest that in women a vaginal examination may enable us to explore the iliac regions as well as the ovaries and tubes.

Dr. W. W. Keen said: I do not wish to be understood as advocating indiscriminate laparotomy in cases of peri-cæcal inflammation. I attempted to draw a distinction between those cases in which the pus is evidently in the iliac fossa, where the lateral incision is the proper one, and those cases in which examination by the rectum, and the vagina in women, shows that the pus has not been limited to the iliac fossa, but is in the cavity of the pelvis, where a median laparotomy is the better operation.

Dr. C. Wirgman said: I rise merely to emphasize one symptom mentioned by Dr. Pepper, and that is, the extension of the pain into the genitals. I had one case in which the pain radiated down the inner and outer aspects of the right thigh. In that case, which terminated fatally, the autopsy showed a concretion, but no foreign body. I had cautioned the utmost quiet. The patient was, however, a restless child, and on the eighth day flung himself from one side of the bed to the other. This was at once followed by excruciating pain, for which it was necessary to administer ether.

Dr. Musser said: I have but a word to say in conclusion. I do not deny that typhlitis occurs. I wished simply to emphasize the relative importance of appendicitis as compared with typhlitis. Typhlitis may occur just as inflammation in other parts of the colon may.

I am glad that Dr. Osler referred to the relations of the peri-cæcal abscess to the peritoneum. In my hurried remarks, I neglected to mention it. It must be borne in mind that the danger of a peri-cæcal abscess depends entirely upon its relation to the peritoneum. When intimately connected with it, or rupturing into the peritoneal cavity, the danger becomes imminent.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 26, 1887.

The President, Laurence Johnson, M.D., in the chair.

Dr. J. S. Warren read a biographical sketch of the late Dr. William M. Chamberlain, whose name had become connected with obstetrics and gynæcology.

Dr. G. H. Fox read a paper on

The Value of Resorcin in the Local Treatment of Acne.

Certain cases of acne, he said, could be treated successfully almost solely by hygienic measures, while others required some local applications. The former class included cases in which the disturbance was principally a vascular one; the eruptions on the face were not numerous, and when one tried to press out the comedones the skin was made worse; the face became flushed after eating and on slight excitement. The second class of cases were of an indolent nature; the skin was thick, dry or greasy; there were numer-

ous comedones. In these, dietetic and general hygienic measures alone would not cure; it was necessary to make some local stimulating application, and of this kind there were many. There were the sulphur and the mercurial ointments and lotions, but green soap he regarded as much better than these. But more efficient still was the remedy suggested by Dr. Metcalf, chrysarobin. To this, however, there was a strong objection in its discoloration of the skin and in its odor. Having the same effect, but not possessing its objectionable features, was resorcin. This remedy applied to the skin had an effect similar to carbolic acid, in that it caused a benumbing sensation, was more or less a caustic according to its strength, and in finally causing the thick epidermis to come away, leaving a thin, new skin.

Dr. J. Leonard Corning then read a paper on

The Treatment of Chorea by Cerebral Rest.

In this paper the author first reviewed briefly the history of chorea, its symptoms, its causes, and then gave its treatment, more particularly that by cerebral rest. Most of these patients, he said, were children of whom their parents expected much; who thought they possessed superior intellectual powers, and did what they could to stimulate them to thought and to study. They seemed to be possessed with the idea that a person in order to think must be acquainted with all the thinking which had been done by anybody else, and these nervous, excitable children were given numerous and difficult studies which an adult could hardly master. Choreic movements could be generated by stimulation of the gray matter of the cord, particularly of the posterior portion, and of the gray matter of the brain, particularly of the basic ganglia and cortex. As there was more or less disturbance of mind in these cases, and as the cortex was conceded to be the seat of the mind, it could be inferred that the cortex was disturbed in its functions in chorea. Dr. Corning had found that cerebral rest was the important object to be obtained in these cases, and this could take place only with the prolonged abolition of consciousness in sleep. Sleep could be secured by habit, for persons who were accustomed to take but a limited amount could, by accustoming themselves thereto, spend twelve or sixteen of the twenty-four hours in sleep. But this habit could not be at once established in choreic children; and in leading them up to the ideal point of cerebral rest he gave them bromides in increasing doses, and when the hour for sleep arrived they were put in a darkened room, away from light and noise. He also employed galvanism to the head. A rubber band was first placed around the scalp to render it anæmic, and ice water was also applied. A farinaceous diet was recommended in most cases. He did not always employ compression of the carotids. He gave arsenic, in the form of Fowler's solution, in increasing doses three times a day, and had in some cases carried it up as far as eighteen drops at a dose. Where peripheral irritation existed, as in the form of a phimosis, it should be removed.

Dr. David Webster spoke of the influence of errors of refraction and of insufficiency of certain sets of muscles of the eyes in causing chorea, and said he had benefitted or cured some cases by measures directed to the correction of those difficulties. But he thought it was claiming too much to say that all cases of chorea were due to any one sort of peripheral irritation.

Dr. Koplik had practiced cerebral rest much in the manner described by the author, with advantage in cases of chorea.

The President had seen two cases of chorea which he could justly attribute to an attack of rheumatism. The patients being run down in health, he would not think of giving farinaceous, but rather nitrogenous food. He would not recommend bromides in all cases, for they did harm in some by deteriorating the quality of the blood.

Dr. Carpenter had seen one case of chorea of such severity as to lead to a fatal issue. Eminent writers were so nearly equally divided on the question of the value of the arsenical treatment that we were left in doubt with regard to it. Certainly it could not be considered as a specific.

—Drs. Crook and Son, of Northfleet, have had marvellous results in the treatment of diphtheria, even when apparently hopeless, by the administration of a solution of *ferri et ammonii citras*, one part in eight of water, of which small doses were exhibited every two hours. In cases where the age gave no control, about half a drachm was allowed to slowly trickle down the throat. Where the patient, of about ten years, was able to guide the swallowing, a drachm of the solution was used with marked and rapid effect. Under this treatment they have not lost a case, and they consider that it deserves a generally extended trial.—*Quarterly Therapeutic Review*, Oct. 1, 1887.

Hospital Notes.

MATERNITY HOSPITAL OF PHILADELPHIA.

SERVICE OF BARTON C. HIRST, M.D.

Ischio-rectal Abscess Recurring with every Labor; Fœtus showing both Sacral and Cervical Spina Bifida.

The following case is of some interest, from the rather rare nature of the complication in the puerperal state, and from the very unusual deformity presented by the fœtus: namely, a cleft spine and meningocele involving the cervical vertebræ, as well as a spina bifida in the usual situation, dividing the sacral bones.

Mrs. McD., thirty-five years old, who had had eight children, gave birth to a premature stillborn infant in the eighth month of pregnancy, which weighed four and a half pounds. Occupying the whole length of the neck behind was a fluctuating tumor, which on dissection proved to be a meningocele, arising from a cleft in the cervical vertebræ. The exact number of bones involved is not given in the notes taken more than a year ago. Over the sacrum was another very large meningocele. The woman, being questioned, confessed that she had been infected with syphilis some years before. The puerperal state was uncomplicated until the tenth day, when the temperature rose to 100.8°, and the woman complained of pain about the anus. Examination then showed an area of redness and induration to the left of the anus. A free semicircular opening around the border of the sphincter ani was made, dressing forceps and grooved director were pushed up along the rectum about an inch, the abscess was opened, and about two ounces of very fetid pus evacuated. No communication between the abscess and the bowel could be discovered. The temperature fell at once, and the woman made a speedy recovery. She positively declared that, after every preceding confinement, the attending physician had been obliged to open an abscess in this same region: a statement which was supported by numerous old linear scars about the anus.

—Dr. R. A. F. Penrose has resigned the Professorship of Obstetrics and the Diseases of Women and Children in the University of Pennsylvania. This resignation is to take effect at the close of the current session.

PERISCOPE.

Curious Vaso-motor Phenomena of Typhoid Fever.

Dr. Angel Money, in the *Lancet*, December 3, 1887, says that, in many cases of typhoid and rheumatic fever, curious vaso-motor phenomena may be detected in the skin; and these, he thinks, may be grouped in one or the other of the following classes. In the first class he places the spontaneous vaso-motor phenomena, by which he means such as may be witnessed without further irritation or stimulation than that which attends the mere exposure of a surface of the body or limb on which observation may be made. If it be the surface of the abdomen, this may be found for the most part of a pinkish hue, such as tends to obscure the presence of rose-spots, if such be present; but, scattered here and there through the red tint, may be seen areas of whiteness, which present a distinct and striking contrast with the general tint, and are, moreover, characterized by varying in distinctness, being whiter or less white at one moment than at the preceding or succeeding moment. If to such a skin, under these circumstances, the additional condition be added of a slight mechanical, electrical, or thermal stimulation, it further happens generally that the stimulated area or line turns white or ivory tinted after the lapse of a rather long latent period, which varies in different cases and at different times, for unknown reasons, but is generally measurable by seconds. The whiteness is not strictly limited to the irritated section, but spreads away from the part stimulated, and in a gradual, decreasing fashion. Moreover, the pallor does not appear abruptly after the period of latency; but the pinkness of the skin gradually gives way to whiteness, and the changing hue is very perceptible. Thus, both in space and time, the phenomenon has a graduation and a duration which are, comparatively speaking, of slow course, and remind one rather of the contraction of smooth, plain, nerveless muscular fibre than the rapid, sharp contractions of the well-nerved voluntary muscle. He states by way of caution that too much stress should not be laid on this feature, although he thinks that it suggests the independence of the phenomena on the nervous system, and their dependence on the mere living undifferentiated protoplasm of the walls of the capillary vessels.

It will also frequently, but not always, be

found that exposure of the skin of the arm and forearm in the same subject presents a contrast with the previously or simultaneously exposed surface of the abdomen, the general tint being white, with irregular patches, sometimes streaks of pink or darker red. When this contrast is evident, and occasionally when there is no such general and spontaneous dissimilarity of appearance, mechanical, and sometimes (always?) electrical and thermic irritation of the skin of the arm will be followed, after a similar, but perhaps generally a trifle shorter, period of latency, by the gradual development of the *tache cérébrale*, or red streak, having the usual characters of that phenomenon. Sometimes the surface of the arm has a general pink tint on first exposing it to the atmosphere, and this may rapidly change to white; but the color of the written characters thereon may be deep red. The contrast in color may be still more remarkable, even in the same case: the writing may be white on the surface of the abdomen, red on the forearm, white on the legs. The author lays considerable stress on the fact that the temperature of the skin and of the body is usually high in cases which present these vascular phenomena; and further, he has most generally observed them in full perfection when the skin has not been perceptibly sweating. But neither increased heat nor especial dryness of the skin are necessary to their production, for the author states that he has seen them very well marked in cases of epilepsy and chorea of uncomplicated and afebrile type. The majority of cases in which these observations were made showed cerebral disturbance, delirium being frequently present at night, for the most part. Nevertheless, the observations were usually made during the day-time, and when the intellect of the patient did not seem to be abnormally affected.

Treatment of Eczema and Psoriasis.

In the *Lancet*, December 3, 1887, Dr. A. S. Myrtle, of Harrogate, a well-known watering-place in England, declares that forty years' experience with eczema and psoriasis has led him to the belief that the former disease is spread by scratching. He goes so far as to say, that if itching is prevented, scratching will cease, and the eczema will be cured. He relates several cases of eczema and psoriasis of a most aggravated type, which were sent to him to undergo treatment with the natural sulphur waters of Harrogate. The author declares that all ointments are filthy and injurious in the eczema which is characterized by diffuse areas with raw surface, which exude serum and pus, and are encrusted with scabs, which leave angry sores on their removal. Dr. Myrtle's treatment, in such a condition, is to employ alkaline sulphur baths, at a temperature of 98° F., once a day, gradually lengthening the duration of the bath. Following the bath, the body is carefully dried, and the affected areas covered with fine sheet cotton-wool, medicated with a preparation of coal tar. His treatment for psoriasis is substantially the same, except that he directs the patient to remain in the bath for as long a time as possible without being chilled, and orders the bath at as low a temperature as the patient can bear. He also orders internally a course of sulphur and chalybeate baths, and expresses the belief that painting the old-standing patches of psoriasis with naphthaline tincture, after the sulphur bath, gives most satisfactory results. This latter application may also be used in the old-standing patches of eczema. He regards a quinine lotion as by far the best preventive against recurrent attacks of eczema.

Treatment of Quinsy.

Dr. W. E. Green, in the *British Medical Journal*, 1887, p. 1151, strongly recommends the following prescription for quinsy:

℞ Tr. aconiti..... 8 parts
Tr. guaiaci.....15 "
Glycerinæ..... 7 "

M.—Dose for an adult, 20 drops every hour until distinct improvement appears, and after that every four hours.

The dose for children is smaller in proportion to their age. Dr. Green mentions of the case of an infant, only eight months old, with quinsy, to which he gave a drop and a half of tincture of aconite every hour for a day and a half, without any ill effect, and which recovered.

Congenital Syphilis Causing Amyloid Disease.

At the meeting of the Pathological Society of London, November 15, 1887, Dr. Hale White (*Lancet*, November 19, 1887) showed specimens of congenital syphilis which had caused lardaceous disease of the viscera, gummata, and fibrosis of the liver, and chronic peritonitis. The patient was a girl seven years old, both whose parents had syphilis, and who herself presented most of the signs of a congenital syphilis. The liver could be felt with a hard rounded edge just above the

iliac crest; the spleen reached below the umbilicus; there was some pain and tenderness in the abdomen; the left eye showed disseminated choroiditis and optic neuritis; the glands in the right axilla were enlarged, and there was a painful node over the head of the tibia; the urine was albuminous, and this decided the diagnosis in favor of lardaceous disease. She improved under treatment, but ultimately succumbed to an attack of acute tonsillitis. The liver weighed 61 oz.; it was hard, rounded, with radiating fibrous depressions all over it; there was also some cirrhosis. At the anterior part was a gumma the size of a walnut; it (the liver) was extremely lardaceous throughout, as was also the spleen, which weighed 16 oz. The kidneys weighed 12½ oz., and both showed tubal nephritis and lardaceous disease. The small intestine and cervical glands were slightly lardaceous; there were several bands of fibrous tissue indicative of old peritonitis. There was no sign of there ever having been any suppuration. The lardaceous deposit was seen very well under the microscope. The case showed three very rare manifestations of congenital syphilis: lardaceous disease, chronic nephritis, fibrous scars and gummata in the liver, in addition to cirrhosis.

Osteoclasis for the Correction of Deformities.

Dr. Dillon Brown, in a paper in the *Medical Record*, December 3, 1887, after stating that osteoclasis was known to the ancients, but that it never gained popular favor until the introduction of ether and chloroform, says that it is just as effective in proper cases as osteotomy, and avoids the dangers from pyemia, secondary hemorrhage, and other accidents which may follow a serious cutting operation. He regards osteoclasis as useful for the correction of: 1. Rachitic deformities of the extremities. 2. Deformities following badly united fractures. 3. Articular deformities resulting from bony anchylosis. 4. Deformities following old dislocations. 5. Certain obstinate forms of club-foot.

With respect to the performance of instrumental osteoclasis, he says that without doubt a certain, and possibly a large, proportion of rachitic deformities of the extremities recover without either mechanical or surgical interference. In no case should constitutional treatment be neglected—good hygienic surroundings, proper food, and cod-liver oil. The hypophosphites are good, theoretically. On this account he would not apply the clumsy mechanical supports in very young children unless the deformity was very much exaggerated, but depend upon general treatment and frequent daily attempts at correction with the hands. The splints do harm, not only by altering the space of the soft pelvis, but by interfering with the action of the already weakened muscles. If the deformity increased in spite of this, he would then apply some mechanical support.

As soon, however, as the bones become eburnated, operative interference is necessary to correct the deformity, and osteoclasis seems to him much preferable to osteotomy. It is just as effective, besides meeting the same indications in a safer and simpler manner. It has been practically demonstrated that the great but temporary pressure brought to bear upon the soft tissues by the osteoclast does no harm, and it has been repeatedly shown, in experiments on the cadaver, that complete control can be had over the point of fracture. In about thirty fractures which he has made with the osteoclast upon the cadavers of children, including the tibia and fibula, the femur and the humerus, the fracture was, without exception, opposite the pressure pad of the instrument; it was practically transverse, and in only one case was there any comminution.

He prefers for bow-legs Rizzoli's osteoclast as modified by Dr. A. T. Cabot, of Boston.

The dangers following osteoclasis in the treatment of the bony anchylosis sometimes resulting from old dislocations are severe enough to make great violence unjustifiable, and warn the surgeon to be cautious in its use. There is not only the danger of separation of the epiphysis, or of fracture near the joint, leaving the limb in a worse condition than before; but large vessels have become adherent to the capsule or the periosteum of a displaced bone, and fatal hemorrhage has resulted from their rupture in attempts to reduce the dislocation. In some cases the muscles have become contracted, and it is necessary to divide their tendons before attempts are made to break up the anchylosis.

In concluding his paper, the author desires to state clearly, that he does not recommend operative measures in rachitic deformities of the extremities until the bones have become eburnated, except in that class of dispensary patients in which the surgeon must correct the deformity rapidly or have no chance to treat the patient.

The principles which guide him in the treatment of these cases are:

1. In children under two years of age, in

which the deformity is not exaggerated, the expectant plan, possibly with frequent daily attempts at correction with the hands.

2. In older children, in which the bones are yet soft, some form of mechanical support.

3. As soon as the bones become eburnated, osteoclasis or osteotomy.

4. Osteoclasis is to be preferred in all cases of deformity near the middle of the long bones, in a large proportion of cases of knock-knee and other deformities near the joints, and only rarely in cases of bony anchylosis and club-foot.

Theory and Practice of the Operation for Radical Cure of Hernia.

W. T. Stoker, Prof. of Anatomy in the Royal College of Surgeons, Ireland, in a paper on this subject read before the British Medical Association, at Dublin, in August, 1887, and published in the *British Medical Journal*, Dec. 3, 1887, says that the open operation is beating other operations out of the field, because it offers certainty and precision, and because it has become a safe operation under the teachings of Lister. He, however, raises his voice against the practice of securing approximation of the walls of the inguinal canal by means of sutures of silver wire; because, when once the hernial canal is closed and consolidated, they become sources of possible inconvenience or danger, or irritation, and also interfere with subsequent application of an artificial support. He declares that the best and most permanent closure depends on the exudation and organization of lymph, and the consequent consolidation and drawing together of the parts, which is assisted by such a plug as the twisted sac is capable of affording. He has adopted the plan of twisting the sac in all his later operations. The following is his method of operating:

The sac is exposed by an incision extending downwards and inwards from the external abdominal ring as far as may be necessary. In ruptures in infants, one inch and a half is generally a sufficient length; in adults or in youths with a large rupture, it may require to be two inches and a half or three inches long. The sac having been exposed, must be carefully and laboriously disconnected from the elements of the cord. This is often a very tedious process, and is best effected with the director and a pair of small scissors. In congenital and infantile herniæ, which constitute the bulk of those operated on in young subjects, the isolation of the sac is often particularly tedious. As soon as the sac is well separated as high as the external ring, and for an inch or so downwards from that point it should be included in two catgut ligatures and divided between them. The lower ligature serves to close the tunica vaginalis if it is a part of the sac, as it generally is in congenital cases, while the upper one seals the peritoneal cavity. If the sac should be of great size, as much of the distal portion of it as is advisable may be removed. The proximal portion of the sac is then seized and twisted, the torsion being carried to such a degree that a sense of resistance is felt. It is difficult to lay down a rule as to the amount of force to be employed in twisting; the object of the operator should be to secure as complete closure of the sac, as close approximation of the walls of the canal, and as much tension and obliteration of the inguinal pouch as is possible, without incurring the danger of the contorted sac sloughing from too severe treatment.

Two sutures of silk are then introduced. Each is made to pass through the pillars and walls of the canal, and to transfix the twisted sac between the inner and outer walls. The sutures should be brought through the skin about an inch from the incision on each side, and the ends of each tied "button" fashion over a leaden plate. Deep apposition is thus secured, and the twists are retained in the sac. Points of interrupted suture are then inserted in the skin, and the wound dressed antiseptically. In very young children a single deep suture may suffice.

He closes his paper by summing up his opinions on the subject of this operation in the following propositions:

1. That, particularly in young children, operation should only be undertaken when minor measures have failed or are inapplicable.

2. That on the ground of its safety, certainty, and precision, the operation by dissection is to be preferred.

3. That twisting the sac is a safe and efficient aid to the operation.

4. That sutures, so far as their use in closing the canal is concerned, serve but a temporary purpose, and that their chief end is to excite a sufficient lymph exudation.

5. That sutures, therefore, need not be introduced tightly, and that trouble from testicular swelling may be thus avoided.

6. That the permanent retention of wires is unnecessary, possibly hurtful, and bad in theory and practice.

7. That while a uniform support to the inguinal region is desirable for some time

following operation, it cannot safely be afforded by a truss furnished with a pad.

It is proper to state, in this connection, that Kendal Franks, surgeon to the Adelaide Hospital, Dublin, at the same meeting of the association at which Mr. Stoker's paper was read, strongly advocated the use of silver wire for sutures. He says he has used it in all his cases except one, a femoral hernia, and regards Mr. Stoker's objections to it as theoretical and unsupported by practical experience.

Treatment of Acute Nephritis in Children.

E. Henock, in a paper on the affections of the kidney in children in the *Charité Annalen*, xii, 1887, S. 638, which is reviewed in the *Centralblatt f. d. med. Wissensch.*, November 5, 1887, says that the treatment of all kinds of acute nephritis is the same. He remarks, by way of caution, that, in the estimation of the therapeutic results of the remedies which have been employed, one must bear in mind that acute nephritis, upon whatever cause it may depend, has an inherent tendency to spontaneous cure. We have, he says, no direct means of holding in check the extension of the disease; but the natural tendency to cure can be materially assisted (1) by absolute rest in bed from the very moment in which the urine becomes albuminous until the albumin entirely disappears; (2) by a milk diet, rigidly and persistently carried out. Milk and farinaceous substances cooked in milk are to be the only food; soup is to be given only in small quantity, meat not at all. Wine is to be employed only when collapse threatens. It is advisable to let the patient drink three or four wineglassfuls of Biliner or Wildunger mineral water daily; and it is also proper to give a mild purgative. Under this simple treatment a large number of cases of acute nephritis will recover in from eight days to a few weeks. Even a slight œdema of the eyelids and ankles is no reason to abandon this method; but more energetic measures are to be taken if the œdema becomes more extensive. Still, one should guard against the employment of stimulating diuretics in these cases, given with a view of increasing the flow of urine, which is always markedly diminished in these patients. On the other hand, purgatives are to be recommened; and, in addition to purgatives, warm baths, followed by sweating. The result of this method depends undoubtedly upon the production of copious perspiration. If perspiration does not occur, then the baths have no effect. It is best to begin the baths with the water at a temperature of 95° F., and bring it gradually to a temperature of 97°–99° F. by the addition of hot water. After the baths, which may last from ten to fifteen minutes, the patient is enveloped in warm woollen blankets until sweating occurs.

The bath is given once a day, and under some circumstances may be persisted in for weeks. Serious injury is never caused by this treatment; only in some rare cases the quantity of blood in the urine is increased. The bath must then be discontinued, and treatment confined to warm drinks. The complication of nephritis with diseases of the lungs or of the heart does not contraindicate the employment of the baths. Other means of exciting sweat, such as wet packs and pilocarpin, do not, on the whole, do as good service in children. It rarely happens that pilocarpin excites more perspiration than the baths, and in such cases it may be employed with proper caution. Other remedies, such as local bloodletting, astringents, etc., do no good at all. In uræmia, pilocarpin not only does no good, but may even be dangerous by provoking collapse. On the other hand, an energetic antiphlogistic treatment achieves rapid and indisputable results; but, where heart failure is threatening, a stimulating treatment is to be employed instead of it.

Transmission of Tuberculosis by Expired Air and by the Atmosphere.

In the *Revue de Médecine*, No. 7, 1887, Cadéac and Malet report that the expired air of phthisical patients, that is to say the water of condensation obtained from it, was neither able to produce tuberculosis in three healthy Guinea pigs, nor in three affected with bronchial catarrh. Nineteen tuberculous rabbits or Guinea pigs were placed in a box, which was divided into two by a lattice work; into the adjoining compartment were placed twelve rabbits or Guinea pigs, in which an artificial bronchitis had been developed: the last-named animals remained free from tuberculosis after two or three months. The authors conclude from all these experiments that the expired air of phthisical patients is entirely harmless. It is otherwise with the air of sick rooms in which is present the dried dust of phthisical sputum or other possible impurities. With the water of condensation of such air, they were successful in obtaining tuberculosis in animals by infection in two cases out of twelve trials.—*Centralblatt f.d. med. Wissensch.*, November 5, 1887.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record. 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

CREASOTE IN PHTHISIS.

In the REPORTER, June 18, 1887, we called attention to the recommendation of SOMMERBRODT, of Breslau, to use creasote in the treatment of phthisis. The good results which he obtained with this medicament have encouraged employment of it in this city, with results which appear to justify his convictions of its usefulness—especially in incipient phthisis. This drug has been given by a number of other medical men, some of whom have been disappointed in its results. In a recent paper, in the *Berliner klin. Wochenschrift*, Nov. 28, 1887, Sommerbrodt states that this disappointment is probably attributable to the fact that the drug was too timidly used. His own experience leads him to the conviction that it should be given in considerable quantities, and pushed almost to the limit of tolerance. He thinks that "the more creasote can be borne daily, the better its effect." He administers it in capsules, containing three-quarters of a grain each. Of these he gives one capsule three times a day for four days; then two capsules three times a day for four days more; then three capsules three times a day for four other days; and so on until he reaches a dose of five capsules three times a day. This makes a maximum of about twelve grains a day. This quantity he finds is usually borne very well, and proves very beneficial to his patients.

Sommerbrodt's opinion of the value of creasote in phthisis is shared by Gimbert, who has said: "If we are asked to define the limits for the employment of creasote in pulmonary phthisis, we would be tempted to reply that we see indications for it everywhere, and contra-indications nowhere." On the other hand Fräntzel says: "Most cases of tuberculosis apply for treatment at a period in which the creasote treatment holds out no promise of success."

It is probable that the truth lies between these two extremes; and we think there can be little doubt that creasote is calculated to do good in a considerable number of cases of phthisis, especially if it be used with some courage, as Sommerbrodt advises.

WASHING OUT THE STOMACH FOR ILEUS.

The treatment of internal obstruction of the bowels has been so much discussed of late that it seems almost tedious to recur to the subject. But, as these obstructions are by no means rare, and as they are apt to occur at most unexpected times, it is important to be as fully prepared as possible for so trying an emergency.

The tendency now-a-days is so strongly toward early surgical interference in cases of ileus, that it seems worth while to call attention to a measure within the reach of every medical man, which often does great good, and sometimes effects a cure. This measure is washing out the stomach. To carry out this procedure it is only necessary to introduce a soft œsophageal tube into the stomach, and to pass through it, with the aid of a funnel, a quantity of water, which will return, if the upper end of the tube be depressed, so as to siphon-out the contents of the stomach.

This method may be adopted—indeed it may be said it ought to be adopted—in all cases of sudden obstruction to the bowels, coming on with the usual symptoms of pain,

nausea, vomiting, and more or less collapse. If promptly appealed to, washing out the stomach will generally alleviate the distressing symptoms, and it may be followed by recovery. If this happy result do not follow, the procedure may be expected to improve the chances of a favorable issue after a subsequent laparotomy, if this be undertaken. The effect of washing out the stomach in cases of ileus is to diminish the contents of the abdominal cavity; to lessen the tension of the bowels; to quiet violent peristalsis; to stimulate the splanchnic nerves; and to remove the cause of the reversed peristaltic movements of the intestine. The latter point is one of the most important in the whole process.

In every way, then, it appears desirable to adopt this method before proceeding to more heroic measures; and we recommend it to the consideration of our readers as part of their preparation for one of the most painful and most dangerous events which can occur in their practice.

SELF-PROTECTION AGAINST BACTERIA.

The question why, if bacteria are almost omnipresent, they do not depopulate the world, is answered by the assertion that they do not thrive in unsuitable media, and that, for their propagation in the human body, its tissues must be in a condition favorable to the growth of the germs which gain an entrance to it. But, in addition to this fact, it has been observed that the blood is not only ill-suited to the growth of many micro-organisms, but even toxic to them.

Some time ago, Wyssokowitsch advanced the theory that bacteria, injected into the blood-current, disappear because they become entangled in the parenchymatous tissue of various organs, and are destroyed (or devoured) by the endothelial cells of the blood vessels.

The correctness of this theory might be doubted from the fact that bacteria often thrive and multiply in the parenchyma of such organs as the spleen. A more recent theory is that the blood itself exercises a repressive or fatal influence upon bacteria. Josef von Fodor, in the *Deutsche Med. Wochenschrift*, No. 34, 1887, describes a series of experiments, the results of which strongly support this theory. He took blood from the heart of a rabbit under suitable precautions, conveyed it into a tube, and inoculated it with anthrax bacilli, controlling this experiment by a similar inoculation of tubes containing gelatine. From all these tubes specimens were taken after intervals varying from a quarter of an hour to an hour, and were tested by cultures in fresh gelatine. By this method Fodor ascertained that the number of bacilli decreased rapidly in fresh blood, and seems to have proved that the blood itself is an unfavorable soil for the bacilli of anthrax at least.

This fact is as reassuring as it is interesting, and explains to a certain extent the immunity from disease which the most of the animal kingdom enjoy in the presence of a host of micro-organs supposed to have the power of propagating disease. It tends to explain the rarity of disturbances due to germ-infection, and the fact that infection is by no means common in surgical operations conducted without specific aseptic or antiseptic precautions.

It is a good thing for mankind, and all animals, that their bodies do not offer an unresisting or propitious harbor to the germs of disease; but that the vital fluid which circulates through their blood vessels has the power of rendering inert or destroying very considerable numbers of these ubiquitous enemies to life and health.

COLLECTIVE INVESTIGATIONS IN REGARD TO DRUGS.

It is announced by *The Pharmaceutical Era* that it proposes to institute a series of collective investigations, selecting for each month a particular query, inviting answers from all who are willing to contribute, and promising to publish the substance of the answers in succeeding numbers of the *Era*. When necessary the *Era* will supply the requisite material for pursuing the investigation.

The first subject proposed for investigation is Dr. Squibb's "physiological" test for the

strength of preparations of aconite — the question being: Is there any uniformity in the susceptibility of different individuals to the peculiar impression produced by aconite on the nerves of the tongue?

The subject proposed for the succeeding month is: Should abstracts be retained in the U. S. Pharmacopœia? Do physicians prescribe them, and are pharmacists in favor of retaining them?

The *Era* justly remarks that these proposed changes in the pharmacopœia should be thoroughly discussed in advance, and desires to include such matters in its plan of collective investigations, hoping to hear from physicians, as well as druggists, in this investigation, and in regard to any topic in which their interests are concerned.

Those pertaining to the manipulations of practical pharmacy will perhaps elicit results of the greatest interest and value, but there are also a multitude of technical and scientific questions which may be discussed with profit. Pharmacology will claim a share of attention, but obviously it can be only the more pronounced characters of drugs that can be considered in such a method. Thus, it is possible perhaps to collect statistical information with regard to such a question as the relative activity of cascara sagrada and buckthorn bark, and even to obtain the practical verdict of physicians, as shown by their prescriptions, regarding the relative merits of these drugs as therapeutic agents. And information collected from observers, the majority of whom may be assumed to be unprejudiced, cannot but be of very great value in such cases as this. Each month the *Era* will announce the subject for discussion in the two succeeding numbers.

We shall look forward with some interest to see how this plan will operate. It has promise in it of much usefulness; and, if it fulfils the promise, we will not delay to lay before our readers the results of the enterprise of the *Era*.

PERICÆCAL INFLAMMATION.

Our readers will observe that in this number of the REPORTER we have reproduced entire three short addresses delivered before the Philadelphia County Medical Society, at a meeting devoted to the subject of pericæcal inflammation.

We would not care to give so much space to one subject, were it not that it is a very important one to every physician, and that in these three addresses the nature, diagnosis and treatment of so-called typhlitis and perityphlitis are described in an admirably clear and concise manner, by men abundantly competent to speak in regard to them.

In calling special attention to this matter, we desire also to commend to other medical societies the plan adopted on the occasion referred to. A subject was selected several months before the time chosen for its discussion; three men were asked to take up each a special phase of it, and the members of the Society were made aware of the fact in time to prepare themselves to join in the discussion or to listen to it intelligently. The result was an unusually large and interesting meeting and a rarely satisfactory presentation of the subject on hand.

LANOLIN AND BACTERIA.

Dr. A. Gottstein, of Berlin, has recently made some interesting experiments in regard to the behavior of pure lanolin toward bacteria (*Berliner Klin. Wochenschrift*, Nov. 28, 1887), and has found that lanolin will not support the life of bacteria, and that bacteria do not penetrate a thin layer of lanolin. The reverse of this is true in regard to lard and suet, in which he found bacteria to thrive, and through which they were able to penetrate.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

The thirty-ninth annual session of the Medical Society of the State of Pennsylvania will be held in Philadelphia, beginning Tuesday, June 5th, 1888. In order for the proper assignment of places on the programme, those who propose to read papers are requested to send the titles thereof, not later than April 15, to the chairman of Committee of Arrangements, Dr. John H. Packard, 1924 Spruce Street, Philadelphia.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

ANATOMY, DESCRIPTIVE AND SURGICAL. By HENRY GRAY, F.R.S., etc. Edited by T. Pickering Pick, F.R.C.S., etc. New American edition, from the 11th English edition. Thoroughly revised and re-edited by William W. Keen, M.D., etc. Royal 8vo, pp. 1100. Philadelphia: Lea Brothers & Co., 1887. Price: cloth, $6.00; leather, $7.00; with colored plates, cloth, $7.25; leather, $8.25.

This new addition of "Gray's Anatomy" has been gone over carefully by Dr. Keen, whose studies in anatomy and whose experience in teaching it make him peculiarly well fitted for such a work. As a consequence, this edition is superior in a number of respects to its English predecessor. This is seen not only in the parts which Dr. Keen has filled out from his own observation, but also in those which he has edited in the stricter sense of the word.

The book, as a book, is very handsome, and we regard it as an especial advantage that a certain part of the edition has been printed with the blood vessels and the nerves colored, as well as the attachments of muscles upon the bones. This not only makes the illustrations more attractive to the eye, but tends to impress what they represent more forcibly upon the memory.

This design was, we believe, original with Mr. Luther Holden, who years ago produced the first edition of his Osteology with the intention of following it up with a work on general anatomy. He was deterred from the execution of this project by the appearance and success of "Gray's Anatomy," which has so occupied the field as a book for students, that of late Mr. Holden seems to have abandoned his original intention, since he has consented to have appended to a work which in that case would be a rival, to his excellent manual on "Medical and Surgical Landmarks."

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS. By ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor of Materia Medica, General Therapeutics and Hygiene in the Jefferson Medical College of Philadelphia, etc. Sixth edition, revised and enlarged. 8vo, pp. xxiv, 802. New York: D. Appleton & Co., 1887.

In his preface, the author says: "This edition of my treatise contains much new matter. The domain of pharmacology is rapidly enlarging by the contributions of chemistry and by the new remedies brought forward by dealers with a view to profit." This sentence illustrates one of the most striking characteristics of the book before us—its inflated verbiage, which perhaps conveys the author's meaning, but in a vague and somewhat incoherent way. Another illustration of it may be found in the sentence in which Dr. Bartholow defines his position in regard to the terms "hypodermic" and "hypodermatic," where he says what he certainly does not mean. It is curious to find an author who is so much concerned about a comparatively innocent term, using so monstrous an one as "urino-genitals" to indicate a class of remedies, or so awkward an one as "stomachal administration."

The scientific value of this book is considerable, in spite of its defects of style. It contains a great deal of useful information, and seems to be abreast of the times. In regard to gleditschine, which was so recently vaunted as valuable addition to materia medica, the author shows great shrewdness in expressing a suspicion, the justice of which has since been fully confirmed.

We are inclined to think the author is a little too hopeful in regard to the effects of drugs in general, and too positive in his statements about them. Still, this very characteristic is probably the secret of the success of his book; for men like to be guided by those who have confidence in their own judgment, and who do not disclose to others any misgivings which they may have in their own minds.

THE RECTUM AND ANUS: THEIR DISEASES AND TREATMENT. By CHARLES B. BALL, M. Ch., Univ. Dub., F.R.C.S.I., etc. Small 8vo, pp. viii, 410. Philadelphia: Lea Brothers & Co. No date. Price, $2.25.

This is an excellent manual, prepared especially for the use of medical students, but calculated to be useful to all sorts of medical men. It gives a clear and very full account of the diseases and malformations of the lower bowel, and of the treatment adapted to each one. The author has studied carefully the best works on this subject, produced on both sides of the Atlantic, and adds to what he has gathered from them the results of his own experience. In questions which are still under discussion, such as the treatment of hemorrhoids by injections of carbolic acid and the best operation for cancer of the rectum, the views of Mr. Ball are, we think, sound and worthy of acceptance; and we can recommend his book heartily to our readers.

The illustrations—of which there are fifty-eight, including four colored lithographs—are for the most part very good. The lithographs are, like most of such illustrations in medical books, more striking than faithful to nature. The type is clear, and the volume, as a whole, convenient to handle, and easy to read.

Pamphlet Notices.

On the Treatment of Felon Without Incision. By L. Duncan Bulkley, A.M., M.D. From the *Journal of the American Medical Association*, July 30, 1887. 8 pp.

On the Existence of "Dermatitis Herpetiformis" (of Duhring) as a Distinct Disease. By L. Duncan Bulkley, A.M., M.D. From the *Journal of Cutaneous and Venereal Diseases*, April, 1886. 12 pp.

Contributions to Gynæcology. Fasciculus I. The Galvanic Treatment of Uterine Fibroids. By Ephraim Cutter, A.M., M.D., LL.D. New York: William A. Kellogg, 1887. 73 pp.

Diet in Cancer. By Ephraim Cutter, A.M., M.D., LL.D. From *Albany Medical Annals*, July and August, 1887. 33 pp.

—Dr. Bulkley says that for many years he has not incised a felon, nor used a poultice in its treatment. The method which has enabled him to pursue this course with satisfaction consists in giving a cathartic followed by Startin's mixture:—Sulphate of magnesia, ʒj; sulphate of iron, ʒi; dilute sulphuri

acid, f℥iv; syrup of ginger, f℥j; and water to make a four-ounce mixture. Dose, a teaspoonful, after eating. In addition to this, he gives calx sulphurata, ¼ gr., in a gelatine-coated pill, every two hours, and generous diet. For local treatment he envelopes the part in Hebra's diachylon ointment. His experience covers a number of cases which he estimates as "a dozen or more" in ten years.

—Dr. Bulkley recognizes the fact that there are diseases of the skin which cannot be exactly classified under any of the varieties designated in works on dermatology; and is inclined to recognize as a distinct group those for which Duhring proposed the name "dermatitis herpetiformis." But he thinks that the herpetic element is so slightly marked that "dermatitis pruriginosa" would be a better term. In this connection it may be noted that German dermatologists do not approve the attempt to introduce these terms in the classification of skin diseases.

—Dr. Cutter presents the histories of fifty cases of tumors, diagnosticated as fibroids of the uterus, upon which he and Dr. Gilman Kimball, of Lowell, Mass., have operated by electrolysis. Dr. Cutter uses strong currents and gets results which encourage him to advocate this method.

—The second pamphlet by Dr. Cutter contains an account of cases diagnosticated as cancer—most of them of the uterus, in which apparently much benefit was derived from pushing the use of food, especially flesh, eggs and milk. Many of these cases are interesting, and some are instructive. But we cannot but characterize as disgusting the author's pointing out his own wife as "Case IX," the details of which are described so fully that few women would care to have their names attached to it.

Correspondence.

Spontaneous Cure of Perityphlitic Abscess.

Ed. Med. and Surg. Reporter:

Sir:—Dr. Dittmer's case of laparotomy for chronic peritonitis, as given in the Reporter of Dec. 17, p. 809, reminds me of a case which I saw in 1857. I was called to a woman about 30 years of age, who had been under the care of an old eclectic who practiced in her neighborhood. He had become frightened at the free discharge of pus from an opening near the navel, and wished me to take the case. The old fellow was inclined to be patronizing, and to give me the benefit of his observation. He said that the patient had a "bealin' in the belly;" that he had been afraid that it was in the os uteri; but now, that it had "broke at the umbillis," he thought her chance was better. I found there was an abscess near the cæcum, with a free discharge of healthy looking pus from an opening at the right side of the umbilicus. I thought it was probably connected with the appendix; but, like the old doctor, I did not know much about it. Antiseptics were then unknown, and drainage-tubes not yet invented. So I prescribed tonics and no local applications except those required for cleanliness. The family lived ten or twelve miles from me. After visiting her a few times, I told them to report any change. I did not hear from her for six months, when I was again sent for. In the meantime the opening at the navel had healed, and another had formed directly over the head of the colon, and had that day discharged two lumps of hardened fecal matter one-third of an inch in diameter. After this, my patient made a rapid recovery. Within a year she was delivered of a healthy child, and she is still enjoying good health. Yours truly, A. Ady, M.D.

Muscatine, Iowa, Dec. 22, 1887.

Chordee a Frequent Cause of Stricture and Chronic Gonorrhœa.

Ed. Med. and Surg. Reporter:

Sir:—Many cases of stricture and chronic gonorrhœa are the result of allowing a patient to be uninstructed in regard to chordee. Many patients with venereal disease are not obliged to rise at early hours, and therefore remain in bed after first awaking until the thoughts of the old haunts excite an erection. With chordee, not only this, but the usual prescriptions of balsam of copaiba and sweet spirits of nitre, etc., in large doses, cause a superabundant secretion of urine, with increased pressure upon the bladder. A patient, who has not been told of this, often lies abed until he is forced by an erection to get up and hold his penis in a cold water bath to reduce the erection.

If, however, all our patients were instructed at the outset to rise early or on first waking, and to immediately empty their bladders, many cases of chordee would be avoided. Further, in gonorrhœa, each prescription should contain some remedy calculated to prevent erections during the congestive stage of clap. For in this condition the mucous membrane cannot stretch freely, on account of the high degree of inflammation, and cannot follow the expansion of the corpora cavernosa, so that small fissures occur, which are increased upon each succeeding erection, and become the sites of small ulcers and sacs, in which pus burrows. This, in my opinion, contributes in no small degree in the formation of strictures of the urethra. I have observed in cases in which chordee frequently occurred, were apt to be tedious and to run a chronic course, often terminating in gleet.

Too many physicians pay no attention to gonorrhœa, other than to give a prescription containing the usual formulæ of copaiba, nitre, etc., and the regulation sulphate of

zinc and rose-water injection, until some four months later the patient returns with gleet, stricture, and all that belongs to a neglected case of clap, saying he has had a tremendous struggle with chordee, balanitis, preputial ulcers, etc. My experience in about one hundred and fifty cases of this disease leads me to believe that patients with gonorrhœa should be kept under rigid rules until they have passed the inflammatory stage at least. Yours truly, C. F. Camp, M.D.

Barre, Vermont.

Pertussis and Jaundice

Ed. Med. and Surg. Reporter:

Sir:—Some three months since the first case of whooping-cough appeared in this vicinity. A number of exposures were made before the nature of the cough was known. The most of the cases were mild; still a number of them were severe. A curious event occurred in the progress of the disorder, which was the appearance of jaundice, in nearly every case of pertussis; while many who had not the cough were afflicted with jaundice. The symptoms were nausea, vomiting, loss of appetite, and a slight rise in temperature. I ascribed the jaundice to gastro-duodenal catarrh, extending to the bile ducts. Under treatment the symptoms rapidly disappeared; without treatment, recovery was slow. In the treatment of the cough, only one remedy was used, and that with marked benefit, not only in apparently shortening the disease, but also in markedly lessening the paroxysms of coughing. This remedy was belladonna: the mother tincture, in half minim doses. The remedy was pleasant to take, and no child refused the small morsel, which has scarcely any taste but that of sugar. The doses were repeated about four times a day. To remove the jaundice and ameliorate the distressing symptoms, I gave nitro-muriatic acid, in small and repeated doses, in sugar and water, with a single tablet containing calomel, gr. $\frac{1}{10}$; podophyllin, gr. $\frac{1}{30}$; ipecacuanha, gr. $\frac{1}{8}$, at bed-time. Under this simple treatment the jaundice quickly disappeared and recovery followed.

There seemed to be something peculiar in the fact that these two diseases were almost always found in company. How to explain the fact satisfactorily, unless it was simply a coincidence, I am at a loss to know. The gastro-duodenal catarrh afflicted nearly every child in the family, and it seemed as if it was endemic or possibly contageous. The late fall and early winter have been very mild, and the temperature quite high for the season, as well as even, with rather a lack of humidity than otherwise. If any one else can see anything interesting in these notes, and can enlighten me, I shall be pleased.

Yours truly, A. D. Bundy, M.D.

St. Ansgar, Iowa, Dec. 20, 1887.

Physician and Pharmacist.

Ed. Med. and Surg. Reporter:

Sir:—I have read the article in December's Reporter, by W. C. Eustis, M.D., berating the pharmacist for exorbitance, and, in fact, for *being* at all. He tells us that the pharmacist could easily be dispensed with, and then, in turn, advises his brother M.D. to keep a dispensing clerk. And pray, who would *he* have for his dispensing clerk? Would he take his untutored student, probably a country patient's son, to "mix and pour" his medicines together, to be retailed to his patients? Could he have the services of an M.D. to mix his remedies? No, his first thought would be, where he could get one who is skilled both in knowledge of materia medica, chemistry, and the pharmacopœia, and a practical knowledge of operative pharmacy.

I do not believe I am far wrong when I assert that fifty per cent. of our physicians, to-day, have no more than a superficial knowledge of chemistry. It has not been required of them to know the details in the manufacture of a chemical compound.

Administration and therapeutical effect are the chief consideration of the physician. Incompatibilities, dangerous and other impurities, adulterations, etc., are the consideration of those who have made them their special study.

Perhaps the practice of Dr. Eustis does not demand the use of an extended list of pharmaceutical preparations. How many physicians are skilled in the making of suppositories? And how many are willing to occupy their time in making them? He says, "water costs the druggist nothing." Possibly that is the limit of his materia medica. According to that statement, the druggist swindles the patient by charging exorbitant prices for water; and for this one reason, in his opinion, the profession of pharmacy should be exterminated.

Such an assertion as his might be received in some places, but in most competitive pharmacy prevents all possibility of its acceptance. According to his ideas I fear the pharmacist would be condemned to become merely a retailer of patent medicines and soda-water.

Yours truly,

E. G. Seibert, Ph.G.

Paterson, N. J., Dec. 26, 1887.

Notes and Comments.

Insanity Following the Use of Anæsthetics in Operations.

Dr. George H. Savage, lecturer on Mental Diseases at Guy's Hospital, London, says (*Brit. Med. Journal*, December 3, 1887) all writers and observers have noticed that one cause alone is very rarely efficient for the production of any attack of insanity, and that usually there are several predisposing causes which may have been in operation for a long time, as well as one or more exciting causes which may have been in action for much shorter periods. To make his own opinion clear, he states the following propositions: (1) The most common form of mental disorder that comes on in such cases is of the type of acute delirious mania; (2) though such mental disorder is generally of a temporary character, it may pass into chronic weak mindedness, or it may pass into (3) progressive dementia, which cannot be distinguished from general paralysis of the insane. The author then reports cases in which alcohol; acute diseases such as scarlet fever, measles, and pneumonia; and in one case a toxic dose of belladonna, seemed to be the immediate exciting cause of an outbreak of acute insanity. All of these patients were predisposed to nervous affections. Coming to the more immediate subject of his paper, he reports several cases in which the administration of an anæsthetic seemed to him to be the immediate cause of insanity. The following is one of the cases, which was communicated to him by Dr. H. Selfe Bennett:

The patient was a young married woman, mother of one child aged ten years, at whose birth transfusion had to be performed and stimulants largely ordered. This patient used to send to the doctor from time to time for hysterical attacks. He found that these were due to alcohol. After three years of medical care she was found to have developed into a chronic drinker. She never had delirium tremens, or any other severe attacks beyond the hysteria (which, by the way, is not uncommon in such conditions). One night the doctor was sent for, to find the patient delirious, conjunctivæ insensible, urine and fæces passed involuntarily; irregular movements of all kinds were being made, and speech was incessant. It was found that she had been as usual in the morning, and had gone to the dentist to have some teeth extracted. Nitrous oxide was used for this purpose, and the outbreak followed rapidly on this. She never regained her senses or recognized her friends. She was in a state of delirious mania for three weeks, then settled into dementia, in which she remains, silly and fat. The points in this case are the acquired nervous instability, the acute delirious mania, with its consecutive dementia, following in a few hours the use of nitrous oxide.

He also refers to several cases of insanity which have followed ovariotomy; but admits that there is at present no evidence to connect insanity in these cases with the administration of an anæsthetic. He concludes his paper by remarking that one or two practical questions arise for the surgeon, one of the most important being whether neurotic inheritance or neurosis in the individual, as proved by previous attacks of insanity, should in any way affect the prognosis in operations, and to what degree it should interfere with operations of convenience not essential for the prolonging or saving of life.

The Contagium of Syphilis.

Dr. J. Disse has been investigating the blood of syphilitic patients, as a result of which he finds, after staining by Gram's method, numerous cocci which are free and active in the blood plasma. These cocci he has cultivated, and states that he has seen the diplococci, which are the active form, produced from them. He has demonstrated the presence of these organisms in twelve cases of syphilis, in ten of which the disease was latent, while in two an eruption existed; on the contrary, he never found these cocci in the blood of non-syphilitic patients, though he often investigated it. Moreover, the same form of coccus was found in Japanese, and in Europeans, no matter whether they acquired syphilis in Japan or Europe, and no matter at what time or place they were examined for the cocci.

If a small quantity of a pure culture is introduced into the blood of animals, the cocci multiply, and can be demonstrated after a long time. Inoculation also produced characteristic lesions, which in turn contained the cocci.

The author gives a detailed account of the post-mortem examination of the organs of animals which had been inoculated with cultures of these cocci, which account will be found in the *Deutsche med. Wochenschr.*, October 13, 1887.

It will, perhaps, be remembered that Lustgarten, who investigated this subject before Disse, found a bacillus which he believed to be characteristic of syphilis. Others, including Disse, do not think that this bacillus is in any way distinguishable from the ba

cillus of præputial secretions, smegma, etc. More recently Doutrelepont, of Bonn, has stated (*Lancet*, October 15, 1887) that he believes the streptococci have no relation to the syphilitic process in hereditary syphilis, but that their presence is due to a septic infection, which the cutaneous and mucous lesions of syphilis render possible.

Improved Caustic Paste.

Dr. Jules Felix, of Brussels, employs the following:

℞	Powdered starch	37 parts.
	Wheat flour	112 "
	Bichloride of mercury	1 "
	Chloride of zinc	110 "
	Iodol	10 "
	Croton chloral	10 "
	Bromide of camphor	10 "
	Crystallized carbolic acid	10 "

Pulverize the ingredients separately, mix in a glass mortar, and add water to produce a paste.

The preparation produces little pain, its action is under perfect control, being proportioned to the duration of the application; it is antiseptic and hemostatic, and produces eschars hard and well limited, which separate spontaneously in a few days.—*Phar. Era*, November, 1887.

The Mechanism of Cyanosis.

At a meeting of the Æsculapian Society of London (*Lancet*, December 3, 1887), Dr. Alexander Morrison read a paper on the mechanism of cyanosis, which included a synopsis of seventy-five collected cases of cardiac malformation. This paper was the sequel of one read before the Society on February 18, 1887, on the case of a child, seven years old, in whom fatal cyanosis was found on *post mortem* examination to have been associated with the following physicial conditions: The ductus arteriosus was closed, the pulmonary artery narrowed to an eighth of an inch, the septum of the ventricles imperfect at its base, the aorta arising at this point from both ventricles. Cyanosis was present from birth, and had become most marked during the last two years. It was attended with severe attacks of dyspnœa. Dr. Morrison regarded the state of the ductus arteriosus in relation to the pulmonary artery as most important. The former channel was open in forty-six of his collected cases, closed in eighteen, and doubtful in the rest. He found that in the first group cyanosis appeared earlier, and the duration of life was shorter than in the second. As regards the mechanism of cyanosis, he considered the chief, though not the only agency at work, to be a diminution of the aspiration exercised by the lungs.

NEWS.

—Dr. Morell Mackenzie returned to London from San Remo, Dec. 30, 1887. He is inclined to take an optimist view of the case of the German Crown Prince.

—Dr. Joseph Leidy has been re-elected President of the Academy of Natural Sciences. The additions last year to the library of the institution numbered 3380 volumes.

—Surgeon-General Hamilton, or Surgeon Stoner of the Marine Hospital Service, will shortly be sent to Peru as a delegate to the Sanitary Conference to be held at Lima.

—An infant, eight months old, has had its leg amputated above the knee in a New York hospital. The child suffered from sarcoma, that appeared below the knee four months after the sufferer's birth.

—Application was made, Dec. 15, 1887, for a charter for the Gynecean Hospital in Philadelphia, the object of the corporation being "to maintain a hospital for the treatment of diseases peculiar to women."

—It is reported that a boy eleven years old went to the New York Dispensary, December 19, to have a molar tooth extracted. After its removal a profuse hemorrhage ensued, and proved fatal in twenty minutes.

—Dr. H. W. Stelwagon delivered a lecture in the course before the Nurses' Training School, at the Hospital of the University of Pennsylvania, Dec. 15, 1887, on the "Hygiene and Care of the Skin in Various Illnesses."

—The low price at which big sales of cocaine have been made in St. Louis of late aroused suspicion among the local druggists. An analysis was made, and the cocaine found to be very greatly adulterated with pulverized borax.

—The matter of international copyright came up in the U. S. Senate, December 19, on the presentation by Senator Hale of a petition for the passage of a proper copyright law, to which were attached the names of Dr. Oliver Wendell Holmes, John G. Whittier, Charles Dudley Warner, Louise Alcott, S. L. Clemens, Bret Harte and others.

—The Board of Trade of the city of Chester, Pa., protests against the continuance of the quarantine station of the port of Philadelphia, in its present location at Tinicum, which is within four miles of the city of Chester, with a surrounding population of 40,000 people; and earnestly recommends the establishment of a national system of quarantine, and the removal of the station complained of at the earliest practicable time.

—The *Chicago Tribune*, Dec. 14, 1887, states that the medical staff of the Cook County Hospital is to be reorganized. On Dec. 13, the commissioners who govern the hospital adopted resolutions requesting the resignation of the present staff, and providing that, after Jan. 1, 1888, the staff of the Hospital shall consist of twenty-one members: viz., eight surgeons, eight medical men, three gynecologists, one oculist, and one pathologist. The staff is to be made up of two members from Rush Medical College, two from the Chicago Medical College, two from the College of Physicians and Surgeons, one from the Woman's Medical College, and fourteen from the Medical Association of the City of Chicago.

—Professor Edgar Crookshank, of the Bacteriological Laboratory, King's College, London, England, has been investigating the disease in cows which Klein has declared to be capable of giving scarlet fever to man, through the medium of their milk. Prof. Crookshank believes that he has discovered this disease to be true Jennerian cow-pox. Cultures made from the discharge of the ulcers upon the cows' teats resembled those of the *micrococcus scarlatinæ* described early in 1887 by Klein so closely as to be apparently identical with them.

A young man who caught the disease from a cow, was seen by Prof. Crookshank when the disease was in its early stage. He presented an umbilicated pock. This pock developed in a most typical manner, and lymph taken from the vesicle produced typical vaccinia in calves.

—The "Sloane Maternity Hospital" and the "Vanderbilt Clinic," Tenth avenue and Fifty-ninth street, New York, were formally dedicated Dec. 29, 1887. The exercises, including an address by Professor T. Gaillard Thomas, M.D., took place in the lecture room of the College of Physicians and Surgeons, which adjoins the new institutions. The Maternity Hospital stands upon a part of the land given by the late William H. Vanderbilt to the College. Mrs. Sloane has endowed all the beds in the institution, so that they will be free perpetually. All the pupils in the New York Hospital Training School for Nurses, in Sixteenth street, will have to serve in the Maternity Hospital before graduation. The Vanderbilt clinic is connected by a covered way with the College of Physicians and Surgeons. It also contains an amphitheatre for demonstrations and a number of private operating rooms.

HUMOR.

A PROMINENT PHYSICIAN has a card hanging in his office, reading: "Consultations from 1 to 2. The other day, a millionaire patient handed him a dollar and a half, and got out before the doctor noticed that some vandal had placed the sign of $ before the figures.

HEROIC TREATMENT.—"Colonel," said a Kentucky lady to her sick husband, "the doctor says the ice water you are taking is doing you so much good that he thinks he will further increase the dose."

"But, my dear," expostulated the sick colonel, "does he understand that it has already been increased to a teaspoonful three times a day?"

HOTEL WAITER—You are late for lunch, sir.

Eminent Physician—Yes, I had to finish my magazine article on "The Laws of Health," so as to get it into the next mail. What have you to-day?

"Hot rolls, clams, plum pudding, apple dumplings, mince pie and fruit cake,"

"Bring 'em all."

ANXIOUS ARKANSAW MOTHER—"Tommy, is that a green persimmon you air eating?" "Yes, maw." "Don't you know it ain't healthy to eat green persimmons on an empty stomach?" "I ain't eatin' this green persimmon on an empty stomach. I ate a peck of 'em before I tackled this one."

A GENTLEMAN of Buffalo said not long ago to his physician, a doctor who has perhaps the largest and most lucrative practice of his profession in Buffalo: "It was a bad day, doctor, when you persuaded me to leave off drinking four years ago." "How so?" said the doctor, "you never looked as well in your life." "Very true!" responded the gentleman, "but my doctor's bill in the mean time has not been $10."

OBITUARY.

DR. FERDINAND VANDEVEER HAYDEN.

Dr. Ferdinand Vandeveer Hayden, the well-known geologist and explorer, died at an early hour at his residence in Philadelphia, December 22, 1887, after a long illness. He had been for over a year a sufferer with locomotor ataxia, which was the immediate cause of his death.

Dr. Hayden was born in Westfield, Mass., on September 7, 1829. He early settled in Ohio, and entered Oberlin College, from

which he was graduated in 1850. He then studied medicine, receiving his degree three years later at the Albany Medical College. He engaged in geological work and soon distinguished himself in explorations in the far west. In May, 1859, he was naturalist and surgeon to the expedition for the exploration of the Missouri and Yellowstone rivers under Capt. Wm. F. Raynolds. He continued in this service until May, 1862, when he joined the army as assistant surgeon of volunteers, being assigned to duty in the Satterlee Hospital, in this city. On February 19, 1863, he became full surgeon, and was sent to Beaufort, South Carolina, as chief medical officer. He was appointed Assistant Medical Inspector of the Department in Washington, in February, 1864, and in September of the same year was sent to Winchester, Va., as Chief Medical Officer of the Army of the Shenandoah. He resigned May, 1865, when he was breveted Lieutenant-Colonel. In the fall of the same year he became Professor of Geology and Minerology in the University of Pennsylvania, which chair he held until 1872, when his duties in connection with the United States Geological Survey necessitated his resignation.

It was due largely to his influence that Congress set apart the Yellowstone National Park as a perpetual reservation. In 1873 the bureau became the "Geological and Geographical Survey," Dr. Hayden continuing in charge until 1879, when the then existing national surveys were consolidated into the "Geological Survey." He was a member of various scientific societies in this country and abroad, being elected in 1873 to the National Academy of Sciences. The University of Pennsylvania conferred on him the honorary degree of LL.D. during the present year. His writings included a large number of government reports, besides numerous scientific papers, and a series of "miscellaneous publications" on special subjects written by authorities in the specialties on which they treat.

W. G. OUCHTERLONY, M.D.

On the 10th of November, 1887, Dr. Wm. G. Ouchterlony died suddenly. He was educated in the schools of Louisville and at the University of Michigan. He took the degree of M.D. at the University of Louisville in March, 1886, and went abroad a few weeks later. He returned home late in the season last year, and went at once into practice in his father's office. He enjoyed the confidence and esteem of a wide circle in Louisville.

DR. MIDDLETON GOLDSMITH.

Doctor Middleton Goldsmith, once a prominent citizen of Louisville, a professor in the Kentucky School of Medicine, and during the war a leading surgeon, having been at one time on the staff of General Grant, died on the 26th ultimo, at Rutland, Vermont, to which place he removed from Louisville soon after the war. Dr. Goldsmith inaugurated the pavilion hospital service during the war, and gained a large share of credit by the introduction of the use of bromine in the treatment of hospital gangrene.

DR. A. B. PALMER.

Dr. A. B. Palmer, Dean of the Department of Medicine and Surgery, and Professor of Pathology and the Practice of Medicine in the University of Michigan, died in Ann Arbor, Friday night, Dec. 23, aged 72 years.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Dec. 25, 1887, to Dec. 31, 1887:

Colonel J. H. Baxter, Chief Medical Purveyor, ordered to inspect the Medical Purveying Depot at St. Louis, Mo. S. O. 296, A. G. O., Dec. 23, 1887.

First Lieutenant Wm. B. Banister, Assistant Surgeon, ordered to proceed to Fort Lowell, Ariz., and report to commanding officer for duty, upon the arrival of Surgeon P. J. A. Cleary at Fort Wingate, N. M. S. O. 135, Dept. Ariz., Dec. 20, 1887.

Changes in the Medical Corps of the Navy, during the week ending Dec. 31, 1887:

Passed Assistant Surgeon C. Biddle, detached from the Marine Rendezvous, Philadelphia, and placed on waiting orders.

Medical Director C. J. Cleborne, detached as member of Medical Examining Board, Dec. 31, and ordered to Norfolk Naval Hospital, Jan. 5, 1888.

Medical Inspector M. Bradley, detached from Naval Hospital, Norfolk, Jan. 5, 1888, and placed on waiting orders.

Medical Inspector J. H. Clark, detached from special duty at Portsmouth, N. H., and ordered as member of Examining Board at Washington.

U. S. Marine Hospital Service:

The Supervising Surgeon-General, U. S. M. H. S., announces that hereafter applications for leave of absence by medical officers and hospital stewards will not be considered while such officers or stewards are under orders to change stations.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ended Dec. 31, 1887:

A. D. Bevan, Passed Assistant Surgeon, resignation accepted, to take effect January 31, 1888, and leave of absence extended to that date. Dec. 31, 1887.

W. D. Bratton, Assistant Surgeon, granted leave of absence for thirty days. Dec. 30, 1887.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Clinical Lecture.

ACUTE PNEUMONIA—TUBERCULOSIS.*

BY NATHAN S. DAVIS, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE CHICAGO MEDICAL COLLEGE.

(Reported by William Whitford, M. D.)

Pneumonia.

Gentlemen:—Last Friday morning, among other cases, I directed your attention to a young man who came in the night before. I had not seen him enough to make a critical examination of his case. He was reported to have been seriously sick before he came to the hospital, and at the time of admission he had all the symptoms of an active grade of malarial fever. His temperature was high; his skin more or less dry, and of a sallow hue, such as is more frequently seen in malarious fevers. His pulse, though soft and lacking force, was quick and of fairly good volume; his mind was wandering. Every now and then he would drop into a drowsy condition, then suddenly awake with spasmodic force and excitement. He was very tall, but not proportionately developed; and the only history we could obtain from him was that he had been engaged with a Wild West Show which had been traveling for some months through Northern Indiana and other sections of the country up to the time he was taken sick. Examining his chest a minute or so before the commencement of our usual Friday morning remarks, and getting from him this short history, I was led to think for a moment that he was probably suffering a severe attack of typho-malarial fever. He had been exposed to malarious influences, had led an irregular life, subject more or less to excitement, variations, ups and downs, in his daily avocation. In going over his chest I failed to detect any evidences of structural or organic disease of the heart. His bowels had a tendency to looseness, requiring one or two doses of turpentine emulsion to restrain them. The character of his pulse, the discharges from his bowels, the rapid breathing, together with the excited, spasmodic arousing from a lethargic condition, led me to infer also that he might have had an inflammatory condition of the membranes of the brain in connection with his febrile condition. But while I was addressing you we heard him cough, and he brought up some characteristic pneumonic expectoration, which immediately led to a more extended examination of his chest; and it was found he had pneumonia involving nearly the whole right lung, with considerable dulness. The sound that was heard belonged to the second stage of the disease; it was not a crepitant râle, but a coarse, mucous rhonchus, with dulness throughout the right side of the chest, and to some extent on the left. The patient was put upon the muriate of ammonia mixture, and a fair, but not extravagant use of quinine, relying upon the muriate of ammonia as an expectorant, and the quinine for its known efficacy in certain grades of pneumonia to help to sustain the tone of the pulmonary vessels and to lessen the amount of exudation and extravasation going on. After having swathed his chest with poultices, it required two or three persons to keep him in bed; he struggled and fought most of the time. In addition to the other remedies we directed carbonate of ammonia; and here we experienced the same trouble as in the application of the poultices. His mental wandering, excitement, and pug-

*Delivered at the bedside in the Mercy Hospital, Chicago, Illinois.

nacious disposition to resist everything given him, rendered it exceedingly difficult to administer medicine or nournishment regularly. The patient died in about forty-eight hours from the time of admission, as I had supposed he would at the time I first saw him.

A *post mortem* examination was made. It was found that nearly the entire right lung was in a complete state of hepatization; a considerable portion of the lower and posterior part of the left was in a similar condition. The upper and anterior portion of the left lung—the part where I put my ear to listen to the cardiac sounds to see whether or not I could detect any structural or organic diseases of the heart—was the only portion of his lungs that remained and was capable of carrying on respiration. There was no disease found effecting the heart. The liver was considerably enlarged, doubtless from the secretion, much the same as it is apt to be found in connection with protracted remittent and malarious fevers, with some fatty degeneration. The spleen, however, was not much enlarged—a feature of interest, inasmuch as it tends to partly overthrow the idea of the existence of typhoid. In following out the examination, there was an intense inflammatory congestion in the coats of the intestines along the lower part of the ileum and junction with the colon. The inflammatory engorgement of the intestines was sufficient to account for the diarrhœal discharges he had, and in laying them open no characteristic enlargement of Peyer's patches could be found; in fact, the usual accompaniment of typhoid did not exist either in the glands of the interior of the intestines, the mesentery or spleen; but there was simply an inflammation of a portion of the intestines together with the conditions we have already pointed out. Almost all portions of the kidneys were studded with hydatid cysts, varying in size, and filled with a yellow serous fluid which bore a close resemblance to urine. There were also some cicatrices on the surface of the kidneys, giving the appearance as though there might have been cysts near the surface, which at some time or other had broken and finally collapsed. The number of cysts pervading both kidneys was quite unusual. The *post mortem* examination in this case revealed a condition of considerable interest to us, taken in connection with the pneumonia, the persistent mental delirium, the general run of fever, and the fatal result. It is undoubtedly true that the patient had contracted strong malarious influences, disposing to the development of fever; and the febrile condition supervening, with its effects upon the general secretory action, rendered the kidneys incapable of carrying on the requisite amount of elimination. The pneumonia probably commenced during the second week of the progress of the attack, and a day or so before he came to the hospital. The improper and inadequate elimination of urea doubtless left elements in his blood which kept up the cerebral excitement to which we have previously alluded—a condition which at any time during the last few days of his life might have brought on uræmic convulsions, followed by coma and death.

Tuberculosis.

This patient's trouble came on about four years ago: at that time he was attacked with hemorrhage, or spitting of blood. The expectoration he raised then, we are informed, was not mixed with mucus; it was a pure, characteristic hemorrhage, such as we see in cases of hæmoptysis or coughing of blood from the lungs. Whatever cough he had at that time passed away in a measure, although he tells us he had more or less of a mild cough all last summer. As we look at him, we observe his general nutrition is below par; he looks weak, pale and emaciated. About a week ago he was attacked with hemorrhage, and brought up, as near as can be ascertained, a half pint of blood; and since that time he has had a continued harassing cough.

He feels pain in the left side of his chest, and, when he coughs, the phlegm he raises is tinged or slightly streaked with blood. When I commenced to examine him, I found his chest enveloped closely with wet cloths, so on that account I did not feel disposed to expose him and subject him to a thorough and protracted examination; perhaps I should have done so. However, I went over his chest enough to convince me that there was something else back of the hemorrhage. You will notice a flattening beneath the clavicle, and that neither side of his chest is filled out. The respiratory sounds are prolonged, exaggerated, and rough on both sides, but a little more so on the left; there is an increased fremitus of voice heard during physical exploration. The history of the case, the characteristic flattening in the infra-clavicular region, and the strong fremitus of voice on this (the left) side—not cavernous, but a strong bronchophony—leaves the way perfectly clear for the inference that this man has got a regular case of slow tuberculosis, the miliary tubercular deposit having commenced there, in all probability, four or five years ago, gradually increasing and invading the lungs little by lit-

tle, tending, during the progress of the disease, to block some of the vessels, giving rise to the hemorrhage to which he referred.

During the progress of the second stage of tuberculosis, the miliary tubercular deposits are undergoing a process of softening, and the surrounding lung tissue is more or less filled by a low grade of pneumonic engorgement, and sometimes a sub-mucous râle may be developed, which is not removed temporarily by the act of coughing, but is developed regularly near the end of each moderate attempt at inspiration, indicating that it depends upon the ingress of air into textures which are more or less filled with a glutinous or viscid fluid. By and by, as the tubercular process continues, the area of congestion in the vessels becomes greater. The mere loss of a half pint of blood amounts to very little; the patient can make up that in a week with a fair appetite and digestion. But it is nevertheless important inasmuch as it points indubitably to obstruction in the pulmonary tissue, and that obstruction, added to the other symptoms, shows very clearly that it is due to a tubercular deposit—a deposit that has not as yet undergone the process of softening; consequently if this patient could go to a milder, more congenial climate, his chances for ultimate recovery would be far greater than they are at present. I have no doubt the miliary tubercular deposit is in a crude state at present, and while there may have been little or no extravasation into the pulmonary tissues, there is danger that it will degenerate and set up a regular suppurative process in about three, four, or six weeks, and while he may not feel sick, be able to dress himself and perhaps walk about the wards some, yet he will continue to cough and expectorate considerable purulent matter, and on the whole getting weaker and more emaciated, and in about six weeks more we will begin to get a cavernous sound at some point of the upper part of the involved (left) lung—in other words, our patient will be in a condition favorable for the commencement of the second stage of tuberculosus disease. By the second stage I mean the stage of softening, disintegration or degeneration of the tubercular masses and the establishment of regular suppurative processes, causing more cough, a quickening of the pulse, probably hectic fever, more night sweats, and soreness in the chest at certain times. When the suppurative process of the disease has about completed itself, the third stage may be said to commence; and during that stage we would probably have an excavation of one or more tuberculous cavities, and a characteristic hectic fever.

In the first stage the miliary tubercular deposit or deposits, as the case may be, are in a crude, unchanged condition; they may exist in a latent state for years — indeed many cases go on for several years without passing beyond that stage. Inspection at this time will usually show a noticeable degree of flattening in the infra-clavicular region, or, as I have informed you on previous occasions, a lessening of the antero-posterior diameter of the upper part of the chest. In case the tubercular deposit is present, or exists only in one lung, the difference between the affected side and that of the other is well marked. If you carefully percuss the chest, so as to get the tone of sound clearly and unmistakably, you will detect a perceptible diminution in the resonance of the affected side, in the infra-clavicular space. In the first stage the physical signs are not merely a production of new sounds, but simply an alteration of the natural respiratory murmur, increased fremitus of voice and diminished resonance on percussion.

The existence of tuberculosis is not always proven by the physical signs alone; they simply prove the existence of something which diminishes the amount of air in the lung, which we examine, and thus renders its structure more dense.

Auscultation in the second stage gives alterations in the respiratory murmur. We notice an irregularity in the development of the inspiratory sound, or its renewal in expiration, and usually there are added more or less mucus râles. The râles at first will be moveable, brought about by mucus accumulations in the bronchial tubes and the passage of air to and fro through it.

The treatment for such a patient as this is first, a change of climate, where he can breathe soft, mild, genial, invigorating air, with good hygienic surroundings, instead of being exposed to a rough, harsh, cold, damp climate, with gaseous, noxious vapors, frozen ground, snow, etc., such as we get in Chicago—a climate where the air is bracing and soothing instead of irritating to the air passages. Were such patients to take up their residence in a good, favorable climate, the disease would not, in a great many instances, extend beyond the first stage, and they would live and enjoy life to a reasonable old age, and attend to business all the while. While in some instances medication will fail, in others it will do good. Medicine is exceedingly useful during the inflammatory attacks; you can fight the disease oftentimes so as to curtail the inflammatory process for a

good while, even without the patient going to another climate. This is partly the reason why many individuals are so reluctant to get into a more favorable country, where the air is bracing, wholesome and soothing. A very large majority of such patients do not comprehend the importance and danger of the situation; they may tell you they do not feel very sick, and on that account it is hard for them to believe that there is anything serious taking place until the second stage is ushered in and fully established, then they begin to have decided night sweats, associated with a rapid loss of flesh, shortness of breath, and commence to think their disease is assuming a serious aspect. The great object in all such cases is to study the initial or primary stage of this tubercular form of disease. I verily believe that this patient commenced to have these miliary tubercular formations or deposits four or five years ago.

Further treatment would consist in giving him such anodyne expectorants as will efficiently allay the irritation, lessen the temporary congestion or inflammatory action as well as possible, for semi-pneumonic processes have undoubtedly been set up around the point where the hemorrhage originated. We put him upon the muriate of ammonia mixture, once every four hours, together with the carbolic acid and iodine mixture alternately every six hours. As an alterative for aiding the muriate of ammonia, counteracting the deteriorative changes in the lungs, lessening further tendency to hemorrhages, I suggest that he be given a pill (three grains of ergotine) twice a day, one after breakfast, and one about eight o'clock in the evening.

[In combating the inflammatory attacks, lessening the cough, rendering the expectoration easy, promoting rest at night, and yet producing very little impairment of appetite or digestion, Dr. Davis recommends also a combination of the muriate of ammonia, tartrate of antimonium and potassium, and sulphate of morphia, dissolved in the syrup of liquorice in such proportions that four cubic centimeters or one teaspoonful would contain four decigrams (gr. vi) of the first, 4 milligrams (gr. $\frac{1}{16}$) of the second, and 5 milligrams (gr. $\frac{1}{12}$) of the third, to be taken every four or six hours, according to the severity of the symptoms.]

—There is a hospital for women at Tashkend, in Turkestan, established by some Russian ladies. It was started some years ago, and the native female population take advantage of it in increasing numbers.

Communications.

THE TECHNIQUE OF OOPHORECTOMY.*

BY CHARLES MEIGS WILSON, M.D.,
PHILADELPHIA.

Although so much has been written on the subject of oöphorectomy that it seems hardly possible to add anything new to our present knowledge on the subject, yet success depends so much on the manner and the details of operating, that it is not perhaps a waste of time to call attention to those methods which have received the stamp of approval of the surgeons who have thus far had the best results in abdominal surgery. The methods detailed below are the *common* property of the medical profession, evolved by the experience of many operators. Some the author first saw used in England and in Germany, others are the result of American ingenuity, and all are of great importance in the production of good results after operating. If to any one man belongs a larger share of credit than to the rest in popularizing these methods in this section of the country, certainly Dr. Howard A. Kelly, of Philadelphia, deserves it.

Preparation of the Patient.—Let us first consider the preparation of the patient. In all cases it is advisable for the operator to have his patient under observation some little time before the operation. This has the double advantage of giving the operator and the patient time to become acquainted with each other, and for the patient to acquire confidence in the operator, and gives the surgeon opportunity to study carefully the case. Too much condemnation cannot be given to hasty and ill-considered operations. The urine should be carefully examined, in order to see that it is free from albumin. Neglect of this rule has doubtless oftentimes been the cause of the patient's death. The gastro-intestinal canal should be in state of healthy function, and the day preceding the operation all portions of the intestine should be thoroughly emptied. This is best secured by the administration of some gentle laxative, such as the compound liquorice powder, in one or two drachm doses; or, if there be some torpidity of the liver, by the administration of one-twelfth of a grain of calomel every hour until the bowels are opened; care, however, being

*Read before the Philadelphia County Medical Society, December 28, 1887.

taken in both cases not to purge the patient, and not to set up any excessive peristalsis. On the morning of the operation, the rectum should be emptied by an enema, and in order to prevent the accumulation of gas in the intestines, and to avoid gaseous distention of the intestines, it is generally best to put into the laxative enema administered a a little turpentine emulsified with the white of an egg. This, as a rule, relieves the intestines of any accumulation of gas present in them, and at the same time is not irritating.

The patient should have, on the morning of the operation, a hot bath, which will add to her comfort and remove any sebaceous matter on her abdomen; it is best to have the patient sponged with alcohol after the bath. Also, on the morning of the operation, the patient should abstain from taking any food, unless it be a cup of strong coffee or a little milk and lime-water. The administration of this food should always precede the time of operation by three or four hours. Above all, it is necessary that the patient have a chance to recuperate her strength and prepare for the mental and physical ordeal of the operation by having a rest in bed of at least three days before the operation, and this is especially important if the patient has come on a long journey and is fatigued with traveling.

The Surroundings of the Patient.—By election, it is always best to operate upon the patient in a hospital, particularly if one have a hospital ward especially devoted to this class of work, in preference to operating upon the patient at her own home. The reasons for this are obvious. In the hospital there are trained assistants and trained nurses, and if the operator be busy with this kind of work, the nurses have no other cases to manage, and are especially trained and especially adapted to this work. Again, too, in the hospital the operator always has his own assistants, who are accustomed to his methods, who understand his wants, and who know exactly what to do at the right moment. In the hospital the operator, as a rule, has an assistant whose especial duty it is to administer the anæsthetic, and where there is an anæsthetizer properly trained for his work and competent, the operator's mind is entirely relieved of the responsibility of the administration of the anæsthetic. He does not have to look at the patient to see how she is doing under the influence of the anæsthetic; he does not have to be interrupted in his work by the patient getting too much ether or chloroform, nor is he bothered with rigidity and stiffening of the abdominal parietes because the patient is not sufficiently under the influence of the anæsthetic.

At the patient's home, especially if it be far distant from the home of the operator, it is not always possible to have either good nurses or good assistants, and the lack of these contributes largely to the difference in the mortality rate in operations done at the patient's home and those done in hospitals especially adapted to this work. Again, in the hospital the operator has time to investigate thoroughly the patient's case, and to weigh all the points *pro* and *con*, whereas at the patient's home he is often obliged to operate hastily, and with a diagnosis formed after a hasty inspection of the patient and study of her case, which is oftentimes not confirmatory of the diagnosis of the regular medical attendant. Prior to the operation, it is better that the patient should have a room remote from the operating-room, with all its appalling armamentarium and paraphernalia, in order that she may not become frightened or worried by seeing the preparations for the operation. It is best on the morning of the operation to bring the patient to a room adjacent to the operating-room, where she may rest until the anæsthetic is administered. The room should be bright, cheerful, airy, and spacious, and should have pictures on the walls, or something in the room to divert the patient's attention. The patient should also be constantly attended by a nurse during the hours preceding the operation, in order that she may not become lonely and allow her mind to dwell upon the operation. It is best, both before and after the operation, to exclude rigorously the friends and relatives from access to the patient, and to have the patient give herself up entirely to the operator, in order that he may control her movements without the interference of relatives or friends.

The Operation.—The room for the operation should, when possible, have walls and floors which can be thoroughly cleaned and disinfected, in order that the operation may be conducted in an aseptic atmosphere. For this purpose, the author's own operating-room has tile floors and glazed tile walls, so that the whole place can be flooded out with water, and placed in a thoroughly clean condition. An operating-table of plain wood, painted, resembling in size and shape the ordinary kitchen table, is all that is really necessary. One or two stands of light construction, and upon large castors, in order that they may be readily wheeled from one portion of the room to another, and a chair

for the assistant who holds the patient's limbs, are all the furniture required. A large can containing distilled water, and an alcohol lamp or gas burner under it, so as to maintain the heat of the water at a fixed temperature, and a tube running from the can to the table, so that at any time during the operation the whole operative field can be flooded, is also in the room. The sponges are used over and over again, until the sponge fibre commences to show evidences of disintegration. These are always of the finest quality, and for the most part those which are known as potter's sponges, or thin, flat sponges. For the first time, they are prepared as follows:

All of the dust is first beaten out of them. They are then immersed in a fifteen per cent. solution of hydrochloric acid for forty-eight hours. They are next thoroughly washed until all the acid is removed from their interstices. Then they are placed for half an hour in a solution of permanganate of potassium, 180 grains to five pints of water. This is done in order to bleach them. The hydrochloric acid solution is, of course, for the purpose of removing any mineral matter that may be in their meshes. They are again washed in running water, and placed in a solution consisting of ten ounces of the hyposulphite of sodium, five ounces of hydrochloric acid, and sixty-eight ounces of water. They are allowed to remain in this solution for a period of from two to four hours, until thoroughly bleached. They are next thrown into troughs of running water, where they are allowed to remain for several hours. Afterward they are placed in jars containing solution of bichloride of mercury (1–1000), and hermetically sealed until the time of operation. After an operation, they are washed out in warm water, then soaked in a solution of sodium carbonate, half ounce to a pint of water, for three or four hours, then rewashed in warm water and put back in the 1–1000 bichloride solution, ready for use again. The instruments are all nickel-plated, with the exception of the cutting edges. They are prepared by being first scrubbed with glycerine soap, and then immersed for several minutes in boiling hot water. They are then laid upon towels which have previously been immersed in the solution of the bichloride of mercury (1–1000), and thoroughly dried by superheated steam. They are then ready for use. The needles are kept in a five per cent. solution of carbolized oil. The ligatures and sutures are kept immersed in a solution of bichloride of mercury (1–500); they are always washed in distilled water immediately before being used. For suturing the abdominal wall, silkworm-gut has been found most satisfactory, clamped and held in position by perforated shot. For ligatures, the twisted Chinese silk has been found to be the best. For anæsthesia, chloroform has been used instead of ether, unless the operation is likely to prove a long one. The reason that chloroform is preferred to ether is the author's belief that chloroform, when properly and carefully administered, is nearly as safe as ether, and because with chloroform, as a rule, there is none of the bronchorrhœa and gastric disturbance which usually follow the administration of ether. Where ether is given, it is found that a less amount is required, and that the anæsthesia is more satisfactorily induced and maintained by administering the ether upon the Allis inhaler rather than with the ordinary cone. Where chloroform is employed, it is usually administered by means of the shield devised by Professor Billroth and used in his clinic.

The temperature of the operating-room should be about 75°. It is best to cover all portions of the patient's body with light blankets, with the exception of that portion of the abdomen involved in the seat of operation. An assistant sits at the foot of the operating-table, and receives and holds the patient's limbs, passes the catheter just before the operation, and, when necessary, with the finger in the vagina, lifts ovary, tube, or pedicle up into the abdominal wound, as the operator may desire. A trusted assistant takes charge of the anæsthetic, and does nothing else. The chief assistant stands on the left side of the patient, ready to give immediate aid to the operator.

Immediately preceding the operation, the patient's abdomen is wiped off with a little ether, in order to remove any greasy matter that may be present upon the abdominal wall, and it is then washed with the bichloride solution (1–1000), and carefully dried, especial care being taken to see that all the little folds about the umbilicus are perfectly clean. If there be an abundance of suprapubic hair, sufficient is removed to give a chance for extending the incision downward if necessary. The operator having satisfied himself that the patient is sufficiently anæsthetized—and by sufficient is meant that she is anæsthetized to the surgical degree—the abdomen is opened with a few rapid strokes of the knife, without the use of the director.

The operator can readily judge of the depth of the abdominal wall, and really no care is required until the subperitoneal fat is reached. The abdomen is opened in the median line,

care being taken to strike the linea alba, if possible, so as not to open the sheath of the recti muscles. If we fail to strike the linea alba, no time is lost in dissection in order to reach it; but if we miss it, the abdomen is opened, if need be, through the rectus muscle. The rule with reference to the incision best to be followed is to make it as small as compatible with the removal of the ovary or of the growth. Where oöphorectomy is performed, an incision one and one-half or two inches in length is amply sufficient. On the contrary, where an ovarian cystoma is to be removed, and the tumor is a large one, or, perchance, semi-solid, or where the adhesions are numerous, it is a great deal better to enlarge the incision in order that the growth can be readily gotten at, rather than to attempt its removal without knowing exactly what we are doing, and without having room enough to raise it up through the abdominal wound. No care is taken to prevent the blood from the wound in the abdominal wall escaping into the peritoneal cavity, and although it is always best to avoid allowing the contents of a cyst getting into the abdominal cavity, it is thought best to complete the operation rapidly, rather than to avoid the escape of the cyst contents into the abdominal cavity. If, however, we are dealing with a pus tube, then, of course, the greatest care must be used to avoid the escape of the pus into the peritoneal cavity, owing to rupture of the tube wall. The pedicle is transfixed with an aneurism needle, the penetrating arm of which is at right angles to the handle, and tied with stout, twisted Chinese silk. The loop of the ligature carried through the pedicle is held as the needle is withdrawn, and divided; each half of the pedicle is tied, and then the whole pedicle is tied with the remaining parts of one of the ligatures. The pedicle is severed close to the ligature, care being taken, however, to leave sufficient of the pedicle to prevent the ligature from slipping. An important precaution to take, to avoid secondary hemorrhage, is to hold the pedicle with the Martin forceps for a few moments and then, if there be no evidence of hemorrhage, it is dropped back into the peritoneal cavity. Where there is any tendency to hemorrhage from the pedicle, it is lightly touched with the flat button of the Paquelin cautery. Where the ovary is bound down by adhesions, and there is oozing from those which have been torn asunder, they are lightly touched with the finger, which has been rubbed against a piece of the perchloride of iron. The abdominal cavity is then invariably flooded for about five minutes with a stream of distilled water at a temperature of 100° F. It is surprising to see how, when a patient is profoundly shocked, this intra-peritoneal irrigation with hot water will immediately restore the equilibrium of the pulse and rally the patient from the shock. In operating, care should always be taken not to handle the ovary or the meso-salpinx any more than is absolutely necessary, because, as has been frequently noted, the patient's respiration becomes embarrassed, and oftentimes temporarily ceases during the time that the ovary is in the grasp of the operator's fingers. Where there is a cyst of any size, its contents are aspirated with Mears's trocar; but where the cyst is small, we prefer to enlarge the abdominal wound, rather than to delay the operation by evacuating the contents of the cyst with the aspirator.

The Toilet of the Peritoneum.—First, as noted above, the peritoneal cavity is thoroughly irrigated with distilled water at a temperature of 100° F. The patient is then turned on her side and all the water allowed to drain out that will. She is then again turned upon the back and the peritoneal cavity carefully sponged, the intestines and mesentery being held out of the way with one hand, while with the other the operator carries the sponge attached to a bayoneted sponge-holder, first into the retro-vaginal portion of the peritoneal cavity and then into both iliac fossæ. The sponging is continued until all shreds of coagulated blood are removed, and, until when the sponge is brought up, only a pale pinkish fluid escapes when the sponge is squeezed.

When we are sure that all hemorrhage has ceased within the peritoneal cavity, the intestines, if any have been left out of the abdominal cavity, are carefully replaced and the mesentery is folded over them. If it be necessary to lift loops of intestines out of the abdominal cavity, they should be carefully wrapped in soft towels kept moist and at a temperature of 100° F. Upon the mesentery is placed a thin, flat potter's sponge which extends half an inch or more around all portions of the wound. This is placed there in order to absorb any blood which may escape from the needle punctures. Its centre is grasped by a hæmostatic forceps in order to facilitate its removal after the sutures have all been introduced. A strong, stout needle threaded with a loop of catgut or Chinese silk, in order to snare the silkworm-gut, is used in the introduction of the sutures. The sutures are all introduced from within outward in order to avoid wounding the intestines with the point

of the needle, and the free ends of each suture are held in the bight of the hæmostatic forceps. When the sutures are all introduced, the flat sponge is removed and the central suture is first tightened. It is found that, as a rule, this makes a neater approximation of the edges of the wound. The sutures are fastened with perforated shot. The abdomen is carefully washed off with the solution of the bichloride of mercury (1–1000) immediately the wound is closed. There is then poured over the surface of the wound a liberal quantity of Keith's dressing (twelve per cent. solution of carbolic acid in glycerine). Over this are laid five or six thicknesses of Lister's gauze, and over the first thickness of the Lister's gauze (the one nearest the wound surface) is dusted a liberal quantity of pulverized iodoform or equal portions of iodoform and boracic acid. Over the Lister's gauze is then placed a thick wad of bichloride wool—that is, wool that has been wet with a solution of bichloride of mercury (1–1000) and thoroughly dried. Over this dressing is applied a bandage of opera flannel fastened with safety pins.

After-treatment.—For the first twelve hours after operation, the patient eats absolutely nothing. If, at the end of that time, the patient has rallied from her shock, and there is no hyperpyrexia or other symptoms of evil import, we commence to feed her with weak tea, ice-cold, giving two or three drachms every hour. This we have found by experience to be the best way of quenching thirst and furnishing gentle stimulation without overtaxing the stomach or producing nausea or emesis. At the end of twenty-four hours we commence the administration of food. This is preferably milk, if the patient will take it and the stomach retain it. If the stomach be irritable, we give koumiss or matzoon in place of milk. Unless the stomach rebel, the use of the milk is continued in half ounce doses with a little lime water, and after a few hours it is alternated with beef or chicken tea; on the fourth day, if the patient is doing well, we commence the administration of animal broths and soft food.

The dressing is never changed unless symptoms arise leading us to suppose there is something wrong with the wound, or trouble within the peritoneal cavity. The sutures are removed on the seventh or eighth day. Drainage is never employed, unless we have reason to fear tissue necrosis as the result of traumatism of the operation, or unless we fear hemorrhage into the peritoneal cavity. If symptoms arise which indicate drainage, it is a very easy thing to open the lower angle of the wound, and insert a drainage tube; where a drainage tube is used, glass is the preferable form. Great care must be taken to see that the mouth of the tube is thoroughly closed by a little tuft of the bichloride wool. When it is necessary to remove any fluid contained in the drainage tube, it is best done with the long uterine syringe, and after the removal of any fluid it is well to pour along the sides of the drainage tube a few drops of Keith's solution of carbolic acid and glycerine. As a rule, the patient is kept in the hospital for a week after the sutures are removed, and is enjoined from traveling any distance until a month has elapsed from the date of the operation. The bowels are moved, as a rule, upon the sixth day, preferably by a gentle saline. Recently we have found Rubinat water the best for this purpose, giving a third of a tumblerful as a dose.

Great care should be taken by the operator to know exactly how many hæmostatic forceps, instruments, and sponges are present in the room prior to the operation. It is the duty of the nurse to count over the instruments and have the count verified by an assistant both before and after the operation in order that the operator may avoid the distressing accident which has happened now many times, of leaving a hæmostatic forceps or sponge within the abdominal cavity.

The operation may be performed at any time, with the exception of the menstrual period, and five days before and five days after it.

Complications arising in the after-treatment.—A majority of the cases that die after oöphorectomy perish from sepsis. Where proper care is taken in the preparation and management of the operation to have everything about the patient, including the atmosphere of the operating-room, the patient's body and clothing, the instruments, the dressings, and, above all, the conduct of the operation in aseptic condition, experience has shown that an extremely small per cent. of patients die from this cause. Careful attention to the rules described in this paper will do a great deal to prevent trouble of a septic nature after the operation. Cleanliness is the desideratum, and this is not by any means attained by the use of antiseptic agents. Indeed, the best results have been obtained, not with the use of carbolic acid or corrosive sublimate, but by the use of distilled or plain boiled water. Personally, I take it that the use of carbolic acid is never justifiable, for it can never be used in solutions sufficiently strong to possess aseptic properties without

subjecting the patient to the danger of carbolic acid poisoning. Where, however, septicæmia does present itself it is best combated by reopening the abdominal wound and irrigating the peritoneal cavity with hot water. The septic hyperpyrexia is best reduced by the administration of antipyrin, and when once the temperature is gotten within the safety line it is best kept there by the administration of quinia. In desperate cases good results in the reduction of high temperature may be hoped for from the ice cap. Stimulants must be freely given, and opium or chloral in sufficient doses to control the nervous disturbance which is nearly always present. Where it is necessary to give opium or chloral it is best to give by the rectum, saving the stomach for the administration of food and stimulus.

Peritonitis following the operation is, I believe, generally septic in character; it is best subjugated by the use of salines. Shock after the operation requires the same plan of treatment employed in treating shock after any other operation. The usual means employed are, external warmth and the hypodermic administration of cardiac stimulants, as soon as the patient can swallow a few spoonfuls of hot coffee, will generally be found the best means to counteract the shock.

The Limitations of the Operation.—As this subject was the one which I had purposed bringing before the attention of the society for discussion to-night, permit me to give you the conclusions I have come to in the matter. I believe the operation is justifiable for the relief of ovarian pain, otherwise uncontrollable; for the artificial establishment of the menopause in cases of uterine fibroma characterized by rapidity of growth and exhaustive hemorrhage, and in which all other means have been tried unsuccessfully; for the cure of those cases of hystero-epilepsy which have well-defined menstrual exacerbations, and which have failed to yield to all other plans of treatment; and, finally, for those cases (which abound in every hospital for the insane) in which the mania or mental aberration is evidently dependent upon, or caused by, the act of ovulation. Indiscriminate, or what may be called hit or miss spaying, cannot receive too severe condemnation, and I doubt not but what the same obloquy and censure will overtake in the future the enthusiastic surgeons who resort to this procedure upon the slightest pretext, as overtook in the past those gentlemen who undertook to cure all the ills of suffering womankind by following the example of Baker Brown, in performing clitoridectomy.

Many of the methods herein described are already adopted by the mass of operators, but not a few of them are due to the ingenuity of Dr. Kelly, as I have before stated. The method of preparing the sponges originated, or at least was adopted, in the Pennsylvania Hospital some three years ago, and was brought to the attention of the profession in an article written by Dr. Thomas G. Morton, and published in the Philadelphia *Medical Times*, of November 13, 1886. Also the general subject of the technique of oöphorectomy has lately been well described by Dr. J. Craig Smith, in his work on *Abdominal Surgery*, published by Blakiston, in 1887; and likewise, also, in Hegar's *Hand-Book of General Operative Gynecology*, translated by Grandin, and published by William Wood & Co.

ON THE TREATMENT OF FŒTID CORYZA.

BY SOLOMON SOLIS-COHEN, A.M., M.D.,
PHILADELPHIA.

The obstinate "nasal catarrh," attended with excessive production of thick, discolored and offensive mucoid material, the discharge of which into the pharynx forms one of the most distressing symptoms, is a troublesome condition to treat; yet one which yields in greater measure than is commonly supposed, to active, intelligent, persistent, mild treatment.

I prefer the name proposed by J. Solis-Cohen—fœtid coryza—to the more recent term, "atrophic rhinitis," because the latter designation is not always applicable. I have seen quite a number of cases in which there was little or no atrophy of the turbinated tissues; although it is undoubtedly true that in the majority of cases there is considerable atrophy of these structures—often, indeed, the entire lower turbinated body, bone and all, will have disappeared almost without trace. The name ozæna, frequently applied to this affection, is sometimes made so general, and sometimes so restricted, that I prefer to discard it altogether.

The remarks concerning treatment, that follow, are not concerned with those forms of fœtid coryza which depend upon ulcerative processes, or the presence of calculi or other foreign bodies; in which cases removal of dead bone, or foreign body, is of course indicated, and the particular measures to be instituted will depend upon the extent and situation of disease. When there is but slight

ulceration, or beginning localized necrosis, scraping of the tissues, followed by cleansing and disinfectant measures, may alone be required.

In those cases where the nasal structures are as yet intact, or where there is simple atrophic change, the treatment, as a rule, is very simple; but it needs to be persisted in.

The first principle is cleanliness. No matter what the origin of the masses which are discharged, or which more often remain pent up in the nasal chambers, giving rise to offensive odors, their presence is an additional source of irritation, tending to prolong diseased conditions; and they must be gotten rid of.

Simply spraying the nose by means of an ordinary hand-ball atomizer will not answer. The nasal douche is apt to be abused, or used improperly, if entrusted to patients. The patient should be given an atomizer throwing a coarse spray, and directed to use some simple detergent solution, such as borax, soap bark and tar water, or even ordinary table salt in water (warm) thrice daily, in order to do what he can towards keeping the parts clean; but at first, frequent visits to the physician's office will be necessary in addition, for the performance of manipulations which the patient cannot exercise upon himself.

The passages should be first sprayed thoroughly with a coarse spray of a warm solution of hydrogen dioxide in distilled water (one part of a 15-volume solution to one or two parts of water), and then syringed with warm water, say 100° F., alkalinized with borax or baking soda, to which also a small quantity of the *liquor carbonis detergens* may be added. The syringing must be carefully and gently done, first through one nasal passage, then through the other, anteriorly and posteriorly; the latter procedure being accomplished by means of a curved nozzle reaching up behind the palate. With a little practice these manœuvres may be executed without discomfort to the patient. The masses loosened by spraying and syringing must be expelled by the patient's efforts, and the measures must be continued, supplemented if need be, by gentle swabbing with a cotton wad, until the nasal passages and pharynx are absolutely clean. The fact of cleanliness should be ascertained by rhinoscopic inspection. If the patient makes daily visits for the first two weeks, in an ordinary case, at the end of that time it will be found that it is both easier to cleanse the passages, and that the amount of material to be removed has considerably lessened. The patient will also report that he has had less difficulty in maintaining the cleanliness secured, by his own little performance with the hand-ball atomizer. According to the progress of the case, the patient may soon be instructed to call only every other day, and his own home procedures be augmented by direction to snuff up from the hand, morning and evening, warmed milk, containing a pinch of table-salt. And as the improvement continues, the intervals between the active measures of the physician are gradually lengthened; until, in an ordinary case, at the end of six months the patient is able to keep himself comfortable by the use of the atomizer night and morning.

This persistent cleansing is the essential feature of the treatment. In addition, the individual conditions of different cases suggest a variety of measures. After cleansing, it is advantageous in cases showing signs of sluggish inflammation to apply to the nasal mucous membrane a solution of iodine and carbolic acid in glycerine (one grain each to the ounce) by means of brush or cotton-wad. Very often the insufflation of some disinfectant powder, such as iodoform or boric acid, or a mixture of the two, will materially assist progress.

When, notwithstanding the accumulation of fœtid mucoid or muco-purulent masses, there is reason to believe that the normal moisture of the nasal passages is deficient, the inhalation of the recent vapors of ammonium chloride is quite useful in stimulating the mucous membrane to healthy activity. Inhalation through the nose with exhalation through the mouth, is preferable to the ordinary method of inhalation through the mouth with exhalation through the nose. The apparatus required is very simple and may be constructed for ones self with a hand-ball and a few bottles and glass tubes. It is important to wash the vapor thoroughly to remove any excess of either hydrochloric acid or ammonia.

This measure is particularly serviceable in cases in which the discharge consists almost wholly of dessicated masses of epithelium desquamated in an immature condition. The inhalation of oxygen is often beneficial. Thymol, eucalyptol and other balsamic and antiseptic vapors may also be inhaled. A weak solution of thymol in alcohol may be shaken up with warm liquid cosmoline and the nasal passages sprayed therewith.

Internal treatment is sometimes indicated. In strumous children, arsenical preparations may be given, of which I prefer Donovan's solution. Iodide of iron and cod-liver oil are sometimes useful. Potassium iodide may be given, to cleanse the passages by the flux of an artifical serous coryza, sometimes with

quite happy effect. I usually resort to this measure at intervals during the course of treatment. Cubeb may be administered in the form of the oleo-resin dropped on sugar, or in pill of the recent powder, to gently stimulate secretion during its elimination by way of the nasal mucous membrane. Ten to fifteen drops of the oleo-resin of cubeb three times daily, after meals, is the ordinary dose for an adult.

Diet should be regulated. It is important to forbid patients, especially children and young women, to eat candy, pastry, and sweets. The prohibition must be absolute. Starchy foods should be reduced to a minimum. The functions of the digestive and excretory organs, including the skin, must be carefully watched and maintained at a proper standard. Exercise in the open air and hygiene in general must not be neglected.

By carefully maintaining general nutrition and vigorous function, with the topical measures already described to secure and maintain cleanliness, and such constitutional medication on the lines indicated, as the individual case may require, the case of catarrh that cannot be greatly ameliorated must be exceedingly rare; and what is practically a cure may be obtained in the majority of cases. As a matter of course, the longer the disease has existed the longer it will be necessary to continue treatment. A month for a year, and three months in any case is a fair rule.

It may be necessary for the patient to continue cleansing the parts by means of his atomizer as a part of his regular morning toilet; but that surely is a very little matter in comparison with the discomfort and annoyance which the possession of a fœtid coryza entails upon the patient and those with whom he comes in contact.

I have deferred until now the mention of the cutting, burning and boring methods, happily becoming less prevalent in the management of all forms of nasal disease, in order to mention my conviction that they have often converted a simple case of catarrh, amenable to the mildest measures, into very obstinate cases of the affection now under consideration.

219 South Seventeenth Street.

—Three deaths from yellow fever and seventy-seven from small-pox are reported from Havana, Cuba, for the week ended December 24, 1887.

WOUNDS OF THE CRANIUM.

BY JOHN A. HOUTZ, M.D.,

LOGANSVILLE, PA.

The cases I here report may prove of interest to the readers of the REPORTER, not on account of anything new in their management, but as showing the remarkable and unexpected results sometimes following seemingly hopeless accidents of this character.

Case I.—March 28, 1883, I was called to see a boy, J. W., aged four years, who had been kicked by a horse. I reached the patient about three hours after he had received the injury and found him unconscious, with a compound comminuted fracture of the right half of the frontal bone. The toe of the horse's shoe, which was quite long, struck about the centre of the right half of the bone, driving it into the brain in the form of an inverted cone. Sharp spicula of the orbital plate penetrated the coats of the right eye, and evacuated its contents. I removed all loose fragments of bone, of which there were many, the largest several inches in length, and including the orbital plate. As I removed the fragments, consciousness returned. Lacerated brain oozed out of the wound to the amount of at least a tablespoonful, while it was being dressed. Having removed all loose bone, and cut away the jagged edges, I syringed the wound thoroughly with warm carbolized water. The skin was then loosely approximated with silk sutures, allowing free drainage, and dressed with lint made of old linen rendered antiseptic with carbolized oil. A compress and bandage completed the dressing. The patient was seen and the wound dressed daily until April 22, and after that at intervals of a few days until May 24, when he was discharged, perfectly restored both as to mental and physical condition, with the exception of the loss of the eye and slight deformity at the site of injury. During the whole course of the case, the temperature did not once rise above the normal. He complained of no pain, had a good appetite, and slept well. At one time—I think about the second week—the dressing remaining on longer than usual, there was slight twitching of the left arm; but that disappeared on the renewal of the dressings. The general treatment consisted in a regulation of the diet, having his bowels regularly moved, and keeping him in a cool, quiet and darkened room.

Case II.—W. E., aged nineteen, was caught in a circular saw, March 28, 1887. On reaching him, about four hours after the occurrence of the accident, I found him in

the following condition: A saw-cut wound, extending nearly horizontally around the head from a point slightly to the left and above the occipital protuberance, around the right side of the head, above the ear, and ending below the right eye. From near the posterior point of the cut to the ear, the wound penetrated the skull and brain fully an inch and a half. The cut through the skull was a half inch wide. Brain was freely oozing out of the wound. Inside of the cranium, and in the brain, were hair, saw-dust, pieces of bark and parts of his hat. His left hand was cut entirely through the carpal joint, from back to front, leaving only parts of the soft tissues in front, not, however, severing the radial and ulnar arteries. The joint was laid widely open, and some of the carpal bones were cut into pieces. Hemorrhage was slight. The general condition was that of severe shock. He was comatose; extremities were cold; pulse was weak and irregular. When aroused from his stupor, he complained of pain more particularly in the hand and arm. I gave him, hypodermically, morph. sulph., gr. $\frac{1}{6}$; and atrop. sulph., gr. $\frac{1}{120}$, and small doses of alcoholic stimulants. The hair was carefully removed from the scalp, in the region of the wound. After being cleansed of all foreign substances and loose bone, and the sharp points of the skull cut away, the wound was thoroughly syringed with a 1 to 1000 solution of hydrarg. bichlor., and the scalp brought together with coarse silver wire sutures. The stitches were sufficiently far apart, over the brain wound, to allow free drainage. The dressing consisted of oakum, moistened with the bichloride solution sprinkled with iodoform, a compress of antiseptic cheese-cloth, and a bandage also washed in the antiseptic solution. After the first week, the moistened oakum was also saturated with carbolized oil, and a perforated tin splint put over the dressing to keep it in place. The wound at the wrist, after the removal of injured bone and dirt, was dressed in the same way, and the arm put on an anterior splint. The patient was seen daily, and the wounds thoroughly cleansed with the bichloride solution, and dressed as above stated, until the latter part of May; and after that, at longer intervals, until the date of his discharge, June 18. Antisepsis was carefully applied at all the dressings, and injured and protruding brain removed, either by syringe or by throwing a silk ligature around the base of the protrusion, and cutting it away with scissors. Altogether, several ounces of brain came away at the dressings, besides what was cut out by the saw at the time of the occurrence of the accident. After a few days, the patient's temperature rose to 103° Fahr., and continued for about four weeks at 102° to 103°. During all this time he was wildly delirious, the greater part of the time not recognizing his most intimate friends. His general treatment consisted in a restricted diet, purgatives and aconite to counteract inflammatory symptoms, morphia sulph. and potassium bromide to relieve pain and produce rest. Cold applications were kept continuously at the top of his head. When the patient began to grow weak, the aconite was gradually withdrawn, and the diet made more nutritious. The wound healed rapidly, so that at the end of the second week it was healed to the points where the skull was penetrated; and as soon as brain matter ceased to protrude, that part also closed; so that by the middle of June, the whole cut was firmly united. The wound of the arm also healed very rapidly, and with but slight suppuration. The joint is firmly anchylosed, and the power of extending the fingers considerably limited; but flexion is normal. He is able to grasp any ordinary object. By the time the wounds were closed his mind had entirely cleared up, and his intellectual powers seem as good as prior to the accident. He says he never has headache, and feels in every way as well as he ever did. He is now working on the same saw-mill on which he was injured, and is making a full hand. I attribute the successful issue of these cases largely to free drainage and antiseptics, which were as carefully applied in both cases as circumstances would permit.

REST IN SYNOVITIS OF THE KNEE-JOINT.

BY G. W. FUREY, M.D.,
SUNBURY, PA.

One evening in the latter part of May, 1881, I was called to see L. C——, nineteen years old, female. I found her completely exhausted by pain, fever, loss of sleep, and inability to take nourishment. Some of her relatives and members of the family were standing around weeping, while she lay moaning with pain one minute, and fainting into kindly unconsciousness the next. She had been able to take no material amount of nourishment for several weeks; and no sleep, except as induced by morphine. Examination soon revealed that I had to do with an acute synovitis of the left knee-joint. The last physician who had attended her had told the parents there was no hope, and that he

could do no more, but would see her again if they thought it of any use. It was evident that if anything was to be done, there was no time to waste, so I proceeded to prepare and apply a Baverian splint. The slightest jar in the room was intolerable to the patient, and, of course, the movement necessary to apply the cast caused great pain, as I did not dare to administer an anæsthetic owing to the prostration present. The patient was in a faint most of the time until the cast had assumed considerable stability, when she rested easier, complained less of pain, and, in fact, rallied just in proportion as the knee was afforded equable support and rest. Before the plaster-of-Paris had set, she had fallen off into an easy, natural slumber —the first for a month or more. Her pulse became stronger, her temperature more normal, and every one concerned felt better. It was ten o'clock when the limb was bolstered up with pillows in an easy position, and left to rest.

I remained till midnight, at which time I thought it best to rouse her up. As soon as she was fully awake, she looked around the room, and, with an eagerness that was pitiable, demanded some food. This I allowed her to have in moderation. After eating all I permitted, she expressed herself as feeling "first rate," and dropped away into a nice sleep, which lasted until morning.

At my second visit, twenty hours after the first, I listened to a full history of the case. She had fallen down a flight of seven stone steps seventeen weeks before, striking her knee; although not seriously hurt in other respects, inflammation of the injured knee soon set in, and it gradually became more and more painful and swollen. A physician was called, who remained in attendance for about four weeks, applying almost everything but rest. The case not getting any better, he was discharged, and I was called in. I was shown about a dozen bottles from which she had been taking medicine. Innumerable liniments, poultices, etc., had also been used; but no restraint of the mischievous contractions of the thigh muscles had been attempted, and the consequent flexion of the leg.

At my second visit the patient was complaining of considerable pain, and was rather depressed and discouraged. But when I assured her that the conditions were just what I expected and wished for, she brightened up. I removed the first splint with care, and, although occasioning considerable pain, soon fitted on another, which, of course, gave her immediate relief, and enabled her to sleep well all night. Sometimes it would be once a day, and sometimes every alternate day from this time on till the girl was able to sit up, that the diminution of the swelling would allow motion in the joint, and consequent pain, and I would have to put on a new splint. In three weeks she began sitting up, and in six weeks she was walking with crutches.

There was acute flexion of the joint at first, which I took the pains to reduce while applying splints, so that when I could make no further extension, it was at something more than a right angle. I now discarded the use of plaster-of-Paris, it having occurred to me that I could do with sole-leather splints all I could with the former, and something more, viz.: produce a leverage that by continuous effort would tend to strengthen the limb. This I happily accomplished in the following way: Making as much extension as possible, I cut out of heavy paper two patterns, one for the inner and one for the outer side of the knee. These I trimmed so that when their edges met in front and behind the limb, they neatly fitted to the same extent the Baverian cast had done. From these patterns I marked out on other paper the patterns I was after. This I did by increasing the knee-angle about three degrees. These latter patterns I used in shaping my leather splints. After making these pliable in warm water, I began at the lower part, and with a roller brought the edges together as I slowly and gently ascended the limb. There was not much trouble about it, and when it was at last "on," I was rewarded in seeing a straightening of three degrees. This method was pursued as often and as long as I could accomplish any improvement. It was the middle of August before the limb was as straight as it was safe to leave it, considering the obstinacy and inclination to remain stiff.

In September, while I was deliberating upon the expediency of giving an anæsthetic and forcibly breaking up the adhesions, her father suggested taking her to Philadelphia. I readily acquiesced, and gave him a letter to one of the leading surgeons of that city. She was there placed under an anæsthetic, and the joint was well manipulated. In a few days she returned to her home, bringing me a letter from the surgeon, suggesting that I continue to manipulate as before, confining the joint as it had been. I have no doubt this would have, in a reasonable length of time, resulted in complete restoration of the joint to a healthy condition; but the patient caught a severe cold coming home, which, in spite of all we could do, settled on her

lungs, and resulted in consumption, with which she died about a year afterwards. The knee trouble never occasioned any further discomfort or pain, however; and, although she was obliged to use a crutch or cane, she was thus able to get exercise and fresh air.

The only feature about this case that renders it worthy of being reported, aside from my plan of adjusting the leather splint, is the treatment—or rather the want of treatment this patient was subjected to for so long—seventeen weeks—by the two physicians who had it in charge at first. They endeavored to subdue the local disease with drugs; I did subdue it with *rest.*

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 28, 1887.

The President, J. Solis-Cohen, M.D., in the chair.

After the reading of the papers by Dr. Charles Meigs Wilson and by Dr. Howard A. Kelly, published in this number of the Reporter, the discussion was opened.

Discussion.

Dr. John C. DaCosta said: Believing that many unnecessary operations are done, and that it is better practice to cure a woman and leave her with her organs intact, rather than by a brilliant operation to unsex her, without the certainty and with only the hope of relief, I took decided ground at the last meeting of this Society, in November, against the great number of abdominal sections now being made, including those made for "pain alone" (which is the subject for this evening's discussion), citing these cases to sustain my argument, viz.:

First. That a large proportion of the operations as done, and for the reasons alleged for operating, are unjustifiable.

Second. That the published reports of many cases said to be cured by operation are unreliable. For, though the operator may have been honest in thinking, when he made his report, that he had cured his patient, the after-history of the case sometimes showed failure.

Third. That the spaying of women for pain alone, and for many of the other supposed causes of trouble for which it is done, and in the miscellaneous way in which it is done, is unwarranted.

Having argued these points fully at the meeting a month ago, I this evening only restate my heads of argument, leaving the discussion to those gentlemen who have not yet had the opportunity to express their ideas.

Dr. W. H. Parish said: Twenty years ago very little was taught of the diseases of the tubes, and of any but the more bulky diseases of the ovaries. More recent experience and more recent literature are teeming with abundant evidence that diseases of the appendages, and more especially of the tubes, are of really the greatest frequency. Most usually the affliction is inflammatory in character, and dependent upon catarrh, gonorrhœa, or sepsis. I wish the readers of the papers had spoken of the prevention of these affections, and especially of the means of preventing inflammatory tubal and ovarian disease reaching that stage in which removal by surgical skill is indicated. The duty of the day is to point out the means of prevention rather than to permit professional interest to continue centered in the operation of removal. At the time when removal of the appendages is justifiable, sterility has been already established by the disease itself, and such treatment as will obviate that stage of progress of the disease which indicates surgical interference will also tend to lessen the probability of the establishment of sterility. What is to-day a mild inflammation of an appendage is liable—it may be very quickly—to become a condition even threatening life; and I am confident that some of the measures to-day directed by many against associated vaginal or uterine inflammation do frequently aggravate greatly a latent and subsiding salpingitis and ovaritis. Too irritating an application to a gonorrhœal endometrium will certainly convert a quiescent inflammation of the tubes into a pus-forming salpingitis. The same is true in reference to application made in other forms of endometritis. Gonorrhœa is the most important cause of dangerous salpingitis. The German writers pronounce the catarrhal form of most frequent occurrence, but they find this form most common in prostitutes, and we are most likely to assume, and correctly, that the disease in the prostitute is of gonorrhœal origin.

Hemato-salpinx often endangers life, inasmuch as rupture of a tube containing such altered blood as is found in that affection may originate fatal peritonitis. Now one of the causes of hemato-salpinx is stenosis by narrowing or by flexion of the cervical canal—securing the patulency of that canal may permit the tube to empty itself gradually into

the uterus, just as it does after opening up the vagina or uterus in hemato-metra and hemato-colpos. The inflammatory cases of tubal and ovarian disease are divisible into three groups: one of mild character, on which probably no one would operate for removal; another group, in which the accumulation of pus is so large and the symptoms so grave, that probably all operators would agree as to the necessity for removal; and then there is an intermediate group, in which surgical opinion would be at variance as to the propriety of removal. In this group the tubes and ovaries are in a condition of more or less subacute or chronic inflammation, with extensive adhesions, and probably some cystic degeneration. Physical examination does not always in these cases clear up the indications. The environments of the patient, the symptoms and the progress of the case, after prolonged judicious treatment, must as yet decide the question.

When, after removal of the inflamed appendages, the relief is not complete, or it may be there is no relief, the explanation is to be looked for often in the incomplete character of the removal,—a portion of the tube, especially the uterine portion, or a portion of the ovary, has been left, and this becomes the focus of other trouble.

There are sins of omission as well as commission in reference to this operation, and I believe that the profession has even yet more of commission resting on it. I am not an extremist, and have not operated for removal of the appendages many times.

Dr. Wm. S. Stewart said: I belong to the conservative class. Battey's operation is not a good one in general. There is danger in operating *per vaginam*. In one case we had a hernia. In one case I succeeded in passing a small sound up into a large abscess (of left tube), and recovery ensued after discharge of pus through the uterus. Those cases in which failure to give relief to pain is most evident, are those in which we are most justified in operating (as the results afterward proved). In one obstinate case in a single woman, with hypertrophied ovaries, and obliterated tubes, the patient was slow in recovering, but has at last reached a comfortable state. She was an intolerable sufferer; internal medication, either by mouth, rectum, or hypodermically had little or no effect. Relief promptly followed removal of the ovaries.

Dr. E. L. Duer said: I think this Society can endorse these papers as representing the advanced state of knowledge on these points. Dr. Kelly has emphasized for us the advantage of the educated touch. Dr. Coe, of the Woman's Hospital, of New York, states that but one-fifth of the ovaries removed are diseased. Pain is such a prominent symptom that it can hardly be called a neurotic manifestation. It is often due to adhesions or to pressure, excepting cases of gonorrhœal origin, or pus-containing tubes. This question has resolved itself to me into one of environment. The poor woman who must keep up and at her work, has no relief but by the knife. The rich woman who can be cared for, with rest, and favorable surroundings may be relieved, sometimes, for example, by the patient and persistent stretching of adhesions and restoring the circulation of surrounding parts.

Dr. J. Price said: It has been our custom to operate only for diseased tubes or ovaries, and we always find disease. Perhaps we cannot say that it will be abscess or pus, but it will always be disease. I do not believe that it is possible to diagnosticate everything until the abdomen is open. Dr. Emmet says: "It has been held that, as a rule, little evidence of previous cellulitis can be found when operating for the removal of Fallopian tubes." And that his experience confirms the accuracy of this observation. This has not been my experience. The adhesions have always been quite general when operating for disease only. Dr. Kelly refers to hemorrhage and Dr. Wilson to sepsis. Dr. Martin talks more about sepsis than any other operator, and his details of antiseptic precautions are quite elaborate. His mortality of twelve in seventy-two would stay Mr. Tait's hand. It is time to put this question in proper shape lest some good man be held criminally responsible for wisely and reasonably avoiding these solutions and dressings so highly lauded. We will take the statements of prominent operators. One is that "unless chemical or antiseptic solutions are used, the operator will be beld criminally responsible." Another, that "men operating without solutions, is recklessness bordering on criminality." The opinion and practice of the skilled members of the profession will be incorporated in and make the law governing in all cases. Prof. Leopold has 110 completed ovariotomies—four died of septic infection (three to six per cent.), and he uses solutions. I believe that the great danger is from hemorrhage, not sepsis. The ovary and tube should be delivered, and this leaves but a small stump to be tied. I am not in favor of operating except for disease. He would not trephine for clavis hystericus or take out the eye for the agonizing pain complained of the next day by the same patient

who wants her ovaries removed for abdominal pain. We hear a great deal now of imperfect operation, necessitating a second operation. Mr. Tait and Dr. Keen have reported cases.

Dr. Sinkler said: The operation of removal of the ovaries is of great interest to neurologists, because many of the cases of hysteria and nervous prostration which came under their care are connected with pelvic pain or dysmenorrhœa. Besides Charcot's observations in hystero-epilepsy, relieving the paroxysm by pressure over the ovaries would seem to indicate that in such cases a cure might be expected from removal of the ovaries. The result of the operation, however, although satisfactory in some, is disappointing in a great many cases of this character. I have had under my care quite a number of patients in whom the ovaries had been removed for hysteria, neurasthenia, pelvic neuralgia, etc. One case, about twenty-three years of age, an extreme case of hysteria and a persistent masturbator, was under my charge at the Orthopœdic Hospital and Infirmary for Nervous Diseases. After seven months, being unimproved in every respect, she was discharged, and was taken by her friends to another hospital, where her ovaries were removed. After a few months she again came under my care, and I found her in as bad a condition as ever. The hysteria was as marked, and she masturbated very often. She did not improve in my hands, and I have recently heard of her, after an interval of nearly three years, in a worse state than ever before. Another case, is that of a lady of forty-two years, who, three years ago, had the ovaries removed for dysmenorrhœa, pelvic distress, and general neurasthenia. After a course of test treatment she has improved greatly; but it is an interesting fact that she still has attacks in which she says there is a sensation of uterine contraction and pressure, just as there was before the operation.

In conclusion, while I would hesitate to recommend removal of the ovaries for the relief of pelvic pain alone, I have no question in my mind that there are many cases of hystero-epilepsy and extreme neurasthenia dependent upon violent and prolonged dysmenorrhœa or ovarian pain, in which it seems to me that the operation is not very justifiable, but is decidedly indicated.

Dr. Chas. K. Mills said: The ground taken by Dr. Kelly can scarcely be attacked if, as I understood him, operation should be only undertaken, in the first place, when local disease can be clearly made out, and, in the second place, such disease can nearly always be recognized by proper methods of examination. Certainly, however, in very many cases of pelvic pain, no disease of the ovaries, tubes, or uterus can be recognized, or, indeed, is present. We have true neuralgias of these organs, as we may have of any viscus. Before too much significance be given to the ovaralgia of Charcot, it should be recalled that even in male hysteria, pain in one or the other iliac region has been met with in a number of reported cases. As to the view expressed by Dr. Wilson, that operation is sometimes called for when hystero-epileptic and other morbid phenomena are exhibited at or near the menstrual period, we should hesitate in accepting this dictum. All nervous symptoms are likely to be aggravated or excited in neurotic women at the menstrual period. In the *American System of Practical Medicine*, I have reported two cases of hystero-epilepsy in which the operation of oöphorectomy was performed. In one of these cases clitoridectomy was also performed. The hystero-epilepsy was not cured in either case. My conclusions are given in this work as follows: "With reference to oöphorectomy for hystero-epilepsy, or any form of grave hysteria, it may be concluded: 1. It is only rarely justifiable; 2. It is not justifiable in the case of girls who have not menstruated; 3. When disease of the ovaries can be clearly made out, by local objective signs, it is sometimes justifiable; 4. It is justifiable in some cases with violent nymphomania; 5. The operation is frequently performed without due consideration, and the statistics of the operation are peculiarly unreliable."

We have few reliable statistics with reference to the performance of pelvic operations for the relief of insanity. In these days, when operations are talked about in every house and almost on every corner, cases of ovarian monomania are likely to be met, cases in which the women are determined to be operated upon whether or not; some of these cases are undoubtedly like those of sexual hypochondria or monomania in man, in some of which self-castration is performed. In the wards of the Insane Department of the Philadelphia Hospital, is now a patient who has removed both testicles by successive operations, under the influence of such a monomania. Operation upon the ovaries or tubes, or both, in cases of insanity, should be restricted to those cases in which either local disease of long standing can be made out, or in which the outbreak of insanity can be clearly traced to disease or impaired function of these organs.

Dr. Keen said: In relation to hemorrhage, one little wrinkle may be of value. I have never had the ligature to slip from the pedicle; and this, I believe, to be due to the employment of this method: I pass the double ligature as usual, cut it in half, tie each half of the stump, and then, without cutting the ends, treat each ligature as follows: I thread one end through a needle, and transfix the tissue near by by this end, and tie a second knot. This fixes the ligature in place, so that it is impossible that it shall slip.

Dr. M. Price said there have been complaints of fistula lately—which may be due to imperfect method of introduction of the drainage tube. We usually introduce it well down into Douglas's pouch, well below the bowels. When there has been pus, we believe it to be necessary; if there be little oozing we remove it after a day or two, but otherwise retain it as long as necessary, and have never had occasion to regret it. I do not see what there is to fear.

Dr. Kelly said: The cases cited by Dr. Sinkler and Dr. Mills have a direct bearing upon my remarks, and show how important it is that the gynecologist should frequently seek the counsel of the neurologist. In reply to Dr. Price, I would state that a neglect of antiseptic precautions is criminal. The Society will not, however, understand me by this to refer in any way to a use of *solutions*, but to the antiseptic conscience, which is the creation of this generation, and in abdominal surgery often does its work as well with soap and water. The obstetric pad which I described, has long been in use at my hospital, and I know of nothing antedating my use of it. Extensive follicular degeneration of the ovaries never *per se*, requires operation, but this is often made necessary by the associated symptoms. All my cases have been benefited, while several continue to suffer from pelvic pain, they are entirely freed from the menstrual exacerbations, most have been raised up from chronic invalidism to perfect health, one attaining this not earlier than a year after the operation. In a case of epilepsy with most marked menstrual exacerbations and severe ovarian pain, the epileptic attacks continue, but she is free from pain, and Dr. Kerlin, under whose charge she now is, considers her improved.

Dr. W. W. Keen read a paper on

A Successful Cystotomy after Failure of Suction to Remove a Piece of a Catheter from the Bladder.

The recent suggestion of Dr. De Forest Willard, and Reginald Harrison (*Lancet*, Oct. 29, 1887) to extract foreign bodies from the bladder by the rubber bulb and evacuator of Bigelow's litholapaxy instrument, makes a valuable addition to our surgical resources in these troublesome cases, and is my especial reason for bringing to your attention to-night the following case. The failure of the method in this particular instance was due to special reasons.

J. W., a healthy man, aged seventy-five years, living in Elkton, Md., had suffered for a considerable time with recurring retention of urine, and cystitis following an enlarged prostate. Dr. Charles M. Ellis, his attending surgeon, very wisely taught him the use of the catheter, which he has employed daily for some months. The Nélaton catheter (No. 22 French), which he has employed, having lost its rigidity, he whittled a pine stick to the necessary size, and sought, by means of this, to introduce it into the bladder, November 7, 1887. In the attempt the catheter broke, and a piece, subsequently ascertained to be 4½ inches long, broke off and passed into the bladder. Severe pain and retention followed immediately, and persisted until after I operated upon him. Dr. Ellis, having failed in his efforts to extract the fragment, sent him to me, as the surroundings at his home were most unfavorable for any operation.

Three days after the accident I made similar and repeated unsuccessful efforts at extraction with forceps and lithotrites. I was not even able to detect the fragment.

On November 11th and 13th I attempted to remove it by suction with Bigelow's evacuator. On the last occasion Dr. Willard kindly helped me personally. We repeatedly filled the bladder with warm boiled water, being careful to keep the extremity of the evacuating tube just at the vesical extremity of the urethra, but suction had no effect in engaging the fragment. This was amply explained later by finding that it lay crosswise, and was so long that both ends were held fixed by the walls of the bladder, while the relative rigidity of the short fragment prevented any possibility of its being brought to the opening of the evacuating tube, though we sought for it through the tube by Dr. Willard's forceps. An evacuating tube with a lateral eye gave no better results than one with an opening at the end. I also used a rectal bulb filled with seven ounces of warm water, but all to no purpose.

After debating between suprapubic and lateral cystotomy, I decided upon the latter, in consequence of the observation of Harrison and others, that the prostate sometimes

shrinks after perineal cystotomy, when a tube is retained in place for some time. Accordingly Dr. Wm. J. Taylor etherized him, and I did left lateral cystotomy with a staff. The operation presented nothing unusual. The prostate was markedly enlarged in its lateral lobes, so that I was barely able to get my finger into the bladder. With the ordinary lithotomy forceps I easily seized the fragment by the middle, removed it, and introduced a rubber drainage tube with a flange, by which it was easily retained in place by tapes. His temperature never rose above 99°, and in six days he went home, with my instructions to retain the tube in place for two months, and then to remove it and allow the opening to heal. By this means I hoped to be able to avoid the necessity for the subsequent daily use of the catheter.

December 5, after nearly five weeks retention of the drainage-tube in the bladder, I found that, owing to his feebleness, want of care and cleanliness, the tube was proving a source of irritation and slight suppuration. Accordingly, December 10, I removed the tube. In three days the wound closed sufficiently to cause him to void his urine by the urethra, and he was no longer obliged to rise at night to relieve the bladder. The prostate has shrunk to some extent, so that he no longer needs to use a catheter. Whether this will be permanent, or is only temporary, time alone will determine.

Dr. J. H. Packard, in opening the discussion upon Dr. Keen's paper, said: I have listened to Dr. Keen's account with much interest, and merely wish to call the attention of the Society to the value, in some of these cases, of the suprapubic operation. This is not taught in the schools, and is scarcely mentioned in text-books, except, perhaps, in the way of condemnation. While not an advocate of this procedure to the exclusion of others, I feel that it has been greatly undervalued, and allowed to fall into undeserved neglect. Especially in cases of foreign bodies, and when a long article is placed cross-wise, there may be difficulty in extraction through a perineal opening. Sometimes, either in these cases or in those of stone, such violence is inflicted upon the vesical wall as to increase materially the risk to the patient. I have seen instances in which I could not but think that a fatal result was largely due to this cause. As a rule (to which I know of but one recorded exception), the injection of seven or eight ounces of water causes the bladder to bulge up, the peritoneum being lifted away from it, so as to afford abundant space for direct entry into the vesical cavity. Through the opening thus made, the finger can be introduced and the cavity explored. After the removal of the offending body, the wound can be sutured, except just where the drainage tube—which I have always employed—is passed in. Through this tube the urine flows away freely.

When infiltration of urine occurs, it is, in my opinion, almost, if not quite, always due to the fact that the incision being made at a point too low down, the contraction of the emptied bladder brings the opening just behind the symphysis; the urine is thus obstructed, and finds its way through the meshes of the areolar tissue. Diminution in the volume of the prostate occurs after the suprapubic section, just as Dr. Keen states it takes place after the perineal operation. I could cite four or five cases in which I have noted this; it would seem to be due to the relief of pressure and the cessation of straining.

Dr. Keen said: In this case I had to deal with a known flexible body, and so there was no trouble in the case. But had it been a rigid body, I would have done a suprapubic operation.

GERMAN MEDICAL SOCIETY OF PHILADELPHIA.

Meeting of December 12, 1887.

Dr. Lawrence Wolff read a paper on

"Ptomaines,"

of which the following is an abstract:

He first referred to the long-known toxic effect of decaying cadavers, and to the fact that their toxic effect was attributed to a chemical poison rather than to the transmission of a special micro-organism creating a poison in the new soil. He quoted the work of Pasteur and others and their effects upon medicine. He argued for the specific action of the microbe, from the fact that albuminoids can be preserved indefinitely if protected from them, reasoning that an organized body does not bear within itself the means of destruction or decomposition after death. He stated that other basic substances generated during life, such as the vegetable alkaloids, have great similarity with the cadaveric base developed through the influence of bacteria, and dwelt on the definite relations necessary between agency and soil to develop certain products. He considers the action of bacteria a chemical one, in consequence of which complex molecules are split up into simpler

ones. He recognizes the albuminoids thereof as the necessary pabulum of the microbe; but denies the excretory character of the ptomaine, which he holds to be simply by-products of decomposition. He quoted at length the history of our knowledge of the ptomaines, and accorded to Dupré and Bence Jones the priority of discovery in the isolation of animal chinoidine. Sonnenschein and Sulzer next produced ptomaines resembling atropine and hyoscyamine, while Rorsch and Fassendre next separated a base giving some of the reactions of digitalin. Schwanert also isolated a ptomaine. Dr. Wolff next mentioned the labors of Francisco Selmi and his work in various poison cases, and those of Liebermann, who obtained a coniine-like ptomaine, as did Brouardel and Boutmy, who claimed for ptomaines the power of reducing potassium ferricyanide—a claim which was soon proven fallacious.

After again referring to the vast labors of Selmi, Dr. Wolff proceeded to the consideration of pathological ptomaines. He claimed by analogy that, as the action of alkaloids is determined by their chemical structure, so must that of ptomaines be. And as special micro-organisms produce specific bases, he argued that the type and course of infectious diseases could in this way be explained. Thus, he said, pathology has fallen to the chemist, as was predicted by the late Austin Flint. He laid stress on physiological experiments made with ptomaines, and contended that when once the specific poison of a disease is known, the antidote will be indicated by its physiological action. He referred to Nencki as the first who furnished pure ptomaines, and then to the exhaustive labors of Brieger, in regard to the poisonous action of peptones and the conditions favoring the development of ptomaines. Dr. Wolff referred to the tyrotoxicon of Vaughan, and laid stress on its importance as a forensic ptomaine, and one pathognomic of cholera infantum. He then in a *résumé* dwelt on the generally transient character of the ptomaines and their instability as chemical bodies. He asserted that the true pathological ptomaines will be found in the pulmonary exhalations, and stated that he is engaged on experiments with a view to test his theory.

In opening the discussion

Dr. Weed related a case of sausage-poisoning, in which the well known symptoms of gastro-intestinal irritation quickly followed the ingestion of the food, but disappeared on the second day. On the ninth day, an attack simulating cerebro-spinal fever appeared, with headache, vomiting, retraction of the neck, delirium, spastic contractions on irritation of all the voluntary muscles, acetonuria, and death by failure of respiration. The autopsy revealed only hyperæmia of the cerebro-spinal meninges. Now, in considering this case, the primary gastro-intestinal phenomena are readily understood to be those of local irritation. But those appearing after nine days, do they speak for a late intoxication, or for an infection after a period of incubation? Is there any known ptomaine which, introduced into the gastro-intestinal canal, would be so gradually absorbed, and so slowly eliminated, as to exhibit cumulative action at the end of so long a period?

Dr. Formad called attention to the fact that cadaveric poisons are volatile, so that the danger from dissecting wounds diminishes from day to day after death. Virchow and Von Recklinghausen advise waiting until the third or fourth day with the autopsy in all cases of infectious disease. And even healthy tissue, as in sudden death from accident, or taken from the living animal, is highly poisonous, if introduced under the skin. So too is the saliva, of which the serpent virus is but a specialization.

Another reason for delay is the fact that the less dangerous bacteria of putrefaction will ultimately crowd out the specific bacteria of the disease. He confirmed Dr. Wolff's statement that oxygen is necessary for the development of the bacteria—his investigations, made in conjunction with Professor Vaughan, upon the bacteria of diphtheria in milk, having illustrated this fact. In his opinion, bacteriology has as yet offered nothing absolute in the diagnosis of disease, except in the cases of anthrax, tuberculosis, and relapsing fever; and he hopes that chemistry will in the near future give us the pathognomonic principles of disease.

Dr. Mays said: It is not true that all animal poisons are the products of the development of micro-organisms, and cited as instances the toxic effects of saliva, its analogue the serpent-venom, and even the physiological peptones, when introduced under the skin. So too papaotin, of vegetable origin, in which no bacteriological agency is claimed, is identical in its effect with the rattlesnake poison. Could not, therefore, certain cases of ptomaiæmia be due simply to the presence of physiological materials in the wrong place: as, for example, the hydrated albuminoids in the circulation? The poison in Dr. Weed's case was probably the "Wurst-Gift" of Brieger, analogous in its effects to curare.

Dr. Wise called attention to the fact that certain savage nations live almost exclusively on the meat of animals which died a natural death, and whose meat is partially decayed—such as the nomadic Arabs and the Norwegian fishermen—without experiencing any ill effects.

Dr. Miller emphasized the element of susceptibility in the production of the phenomena of ptomaine poisoning, and cited cases, one of tyrotoxicon and one of post-mortem poison, in which only certain individuals experienced ill effects.

Dr. Rosenthal called attention to the fact that in the cases of ergotized rye and fish-pickle, vegetable and animal tissues furnish identical poisons, namely, propylamine and trimethylamine.

Dr. Seiler, in reply to Dr. Wise, said that immunity results from the habitual introduction of toxic elements into the system, as in the case of the poison of insects. He questioned whether the endemic leprosy among the Norwegian fishermen might not be in part due to the very habit cited.

Dr. Muehleck denied the toxicity of saliva, *per se*, quoting the authority of Frerichs, whose experiments showed his own saliva to have been at times toxic, and at others not, and attributed this difference to the demonstrated presence or absence of micro-organisms in the respective observations.

Dr. Collins expressed his belief that ptomaines are constantly produced in the body, and that auto-infection is prevented by the simultaneous production of antagonistic ones.

Dr. Wolff, in closing the discussion, said that in Dr. Weed's case the primary phenomena were due to direct irritation, while the later symptoms were of bacterial origin. There is a remarkable resemblance between ptomaiæmia and curare poisoning. As we are ignorant of the mode of preparing this drug, who knows but what decayed animal tissue may be one of its ingredients? In reply to Dr. Wise's remarks, he called attention to the fact that cooking decayed meat would drive off the volatile ptomaines, and kill the bacteria; and that when such food is taken raw, the process of digestion effects the same result.

—Dr. Gross, of Geneva, has lately experimented with himself in hanging. His experiments established that the sensations were only warmth and a burning in the head, without convulsions. Of course, his experiments didn't go very far.

Periscope.

Sudden Death in Typhoid Fever.

Dewèvre is reported in the *Medical Chronicle*, Dec., 1887, as saying that (*Archives générales de Médecine*, October, 1887) the frequency of sudden death in typhoid fever has been variously estimated by different writers; it probably occurs in four per cent. of the cases. It is most often met with between the ages of 22 and 25, being rare in infants and old people. It occurs in males more frequently than in females, the proportion being rather more than four to one, and often in those who have been previously robust. It is most common in the third week of the disease, the largest number of sudden deaths occurring in the medium form of the disease rather than in the severer or slighter forms. It does not appear that relapses are very favorable to its occurrence. In some epidemics it is more frequent than in others. M. Hardy considers quinine when given in large doses to be a cause of sudden death in typhoid. It generally occurs after some effort, movement, or emotion, and occasionally during sleep. In the majority of cases there are certain premonitory symptoms which foreshadow a fatal issue; but these may be entirely wanting. Amongst the most frequent may be mentioned troubles of the respiratory apparatus, *e. g.*, dyspnœa, the cause of which the most scrupulous examination fails to discover; it occurs and ends suddenly, and is accompanied by a sense of agony closely resembling uræmic dyspnœa. Severe bronchitis and pulmonary congestion are also met with. On the side of the nervous system, syncope and convulsions occupy the most prominent position, while delirium and insomnia are not infrequent. Sometimes suppuration or hemorrhagic otitis complicates the case. Contractures and paralyses of different kinds are also met with. Circulatory troubles occur next in frequency to nervous disturbances, and they play an important part in the production of sudden death, as will be seen later on. Albuminuria is a common complication. Tympanitis has also been known to cause a sudden and fatal issue in typhoid. Sometimes the patient dies suddenly, without any of the foregoing symptoms being present. The frequency of the pulse affords a reliable guide to the state of the heart muscle, especially if the arterial tension be at the same time carefully noted. Hayem regards intermittence of the pulse as significant of impending danger; but the author thinks the danger has been over-estimated, inasmuch as

it frequently occurs at the end of typhoid, and, according to him, indicates that convalescence is approaching. Of all the premonitory symptoms which may foreshadow sudden death, the author regards convulsions (which may be general or local, slight or severe) as by far the most significant of approaching danger.

Post-mortem Appearances.—In 48 cases no lesion capable of causing sudden death was found, but in all the others a sufficient cause was demonstrated. It is interesting to observe that in the great majority of cases the intestinal ulceration was in the process of cicatrization. In sixteen cases the heart was pale, soft, and of a "faded-leaf" color, with fatty and granular degeneration of the muscular fibres. In a few cases proliferating endarteritis of the smaller vessels supplying the walls of the heart was noticed. Myocarditis, endocarditis, ante-mortem coagulation, etc., have also been met with; also, embolism of the pulmonary artery in seven cases. Amongst other lesions may be noted bronchitis and pulmonary congestion and nephritis. Cases of sudden death in typhoid may be divided into two classes, viz., those in which the autopsy reveals pathological changes which are sufficient to account for death; these form two-thirds of the fatal cases. In the other class are those in which no satisfactory cause of death can be discovered. The author thinks that pulmonary embolism and cardiac thrombosis are by no means a common cause of death. Hayem thinks that a peculiar form of degeneration of the heart muscle is constantly present in sudden death from typhoid, the cement substances between the muscular fibre cells being softened. The author does not admit that this change is universal, for in many cases it cannot be found, while it is not unfrequently well marked in cases in which death has occurred slowly; it is also of very frequent occurrence in typhus fever, while in this disease sudden death is not at all common; the same applies to small-pox. In diphtheria, also, sudden death is rare, while cardiac degeneration is very common.

Landouzy and Siredey have advanced the theory that ischæmia of the cardiac walls, due to swelling of the cells of the endothelium of the vessels supplying the heart, is the cause of sudden death in typhoid; but this change is of limited extent, and cannot be accepted as a probable explanation.

—The St. Louis Medical Society is endeavoring to secure sufficient funds to erect a building for their meetings and library.

Distribution and Etiology of Abscess of the Liver.

Dr. D. H. Cullimore, basing his statements upon statistics taken from the Report of the European Army in India from 1870 to 1879, declares (*Med. Press and Circular*) that, in his opinion, the predisposing factors (the greatest of which is prolonged heat) being equal, if we possessed an accurate knowledge of the stations in India, or elsewhere in hot countries, where hepatic abscess is most rife, we should find that they are such as favor most powerfully the operation of chill. Secondary factors are such exercises as are conducive to injury of the liver, already in a state of irritative congestion,—a condition in which rest is essential to resolution and cure. He asserts that the conditions most favorable to chill are:

First. Great monthly, and great daily, and sudden variations of temperature, particularly if associated with a heavy rainfall, following great heat.

Second. Situations on large rivers, particularly in hot river valleys, the river being subject to annual floodings, soliciting exposure to wettings.

Third. Misty and foggy situations on the slopes of mountains with a great rainfall.

Fourth. Situations overtopped by hills, or in the vicinity of hilly or mountain gorges, bare rocks, or isolated hill tops, such being easy of access.

Fifth. Excessive rice cultivation.

A combination of several of these factors is especially dangerous. In the absence of such conditions, it will generally be found that a high mortality from abscess is associated with the presence of cavalry or artillery.

Thirty-five Operations for the Radical Cure of Hernia by Original Methods.

Arthur E. Barker, F.R.C.S., surgeon to University College Hospital, gives (*Brit. Med. Journal*, Dec. 3, 1887) the following statistics of these thirty-five cases, although he admits that it is too soon to speak of the ultimate results as regards permanency of cure:

Of the 29 individuals operated on, 7 have been lost sight of, 20 have presented themselves recently for examination, and 1 has been heard of through competent observers. Of the 3 other cases in which the rupture returned and a second operation was necessary, the result was palpably due in 2 cases to the rapid absorption of the carbolized gut in one,

and of kangaroo tendon in the other; and in the third, which was one of his earlier operations, he was conscious at the time of not having taken up enough of the walls of the canal in his stitches.

None of the remaining 20 cases which have been followed up to date, and in all of which silk has been used, show any sign of return of hernia so far. Three were seen quite well twenty months after operation, 7 between twelve and fifteen months also quite well, and 4 between six and twelve months. It may be interesting to note that in one case whooping-cough, nine months after operation, had failed to reproduce the rupture, but had been bad enough to bring down a hernia on the opposite side, which had been perfectly sound before.

The objects kept specially in view in dealing with the cases of inguinal hernia above mentioned have been:

1. To free the inguinal canal and both rings from the presence of the sac, so that accurate closure might be effected.

2. To strip the neck of the sac from the cord with as little disturbance of the vascular and nervous structures of the latter as possible.

3. To cut the sac across just outside the external ring, and reduce its tied stump well within the internal ring, fixing it there by the same ligatures which close its neck.

4. To close the internal and external rings and all the length of the canal firmly with strong silk sutures.

5. To leave the fundus of the sac undisturbed in the scrotum, so as to avoid damage to the cord, testicle, and their vascular and nervous supply.

6. To get union by first intention everywhere, so that the deep sutures shall remain unchanged, and help to permanently close and control the rings and inguinal canal.

7. To avoid the use of trusses except in cases of umbilical hernia.

The author states in a note, dated November, 1887, that since his paper was read before the British Medical Association, in August, 1887, he has added six other operations to the above thirty-five. Of these, one was femoral and four were inguinal. Of the latter, two were congenital. All healed by first intention, except one, in which there was free suppuration in the scrotum; but the patient, a boy, is now at home well; one is still in hospital, but is quite well. There has been a return of the hernia in two cases in addition to those mentioned above, one in a very fat woman (umbilical), the other in a young man who had been at very hard work without a truss ever since soon after operation.

Laceration of the Radial Nerve in Complicated Luxation of the Elbow; Successful Secondary Suture.

In the *Deutsche Zeitschr. f. Chirurgie*, xxv, 3, Dr. G. Ledderhose reports a case in which he operated on a patient thirty-two years old, who, four months before had sustained a complicated luxation of the right elbow-joint, with laceration of the radial nerve. The injury was followed by high fever and suppuration of the joint, and necrosis of the external condyle of the humerus. Recovery ensued, but with ankylosis of the forearm at a right angle, and complete paralysis of the radial nerve. The muscles supplied by the radial nerve were completely paralyzed, and exhibited marked reactions of degeneration. On laying bare the ends of the nerves which had been torn apart, the proximal extremity was found expanded and united with the capsule of the joint, while the distal extremity was likewise thickened and firmly adherent to the tissues surrounding it, so that the ends of the nerves were separated from each other by a space of from two and a quarter to three and a quarter inches. The ends of the nerves were freshened diagonally, and sewed together, the position of the arm being at an acute angle. The wound healed rapidly by first intention. After the first few days of the operation, the functions of the interossei returned, which before had probably only been injured through œdema of the hand. Eight months later, active extension first become possible. By careful after-treatment, consisting of massage and electricity, the functions of the muscles supplied by the radial nerve had nearly completely returned, but the arm was still ankylosed at an obtuse angle, and there was disturbance of sensibility over an area in the forearm the size of the palm of the hand.—*Deutsche Medizinal-Zeitung*, Nov. 28, 1887.

Caseine as a Basis for Emulsions.

In the *Bul. de la Société de Thérapeutique*, Nov. 13, 1887, Léger strongly recommends the use of caseine in preparing emulsions, claiming that when prepared in this way they may be called "milk in which the butter has been substituted by a medicinal substance." The formula which he recommends is:

℞ Ol. ricini (or any other oil) 20 parts.
Caseini saccharati.....q.s.
Aquæ destillatæ.....100-200 parts.
Aquæ menth. pip.....5 parts.

The saccharated caseine is prepared by mixing purified caseine of cows' milk with bicarbonate of soda and sugar.

MEDICAL TESTIMONY IN SUITS FOR DAMAGES.

Some of the peculiar aspects of medical testimony in suits for damages are illustrated, and some practical reflections are suggested, by a case which is now on trial in New York.

On January 6, 1888, a woman forty-one years old, and with the appearance of an invalid, came before the Supreme Court of New York, claiming $20,000 damages for the results of an injury caused by a fall in in the street, on January 13, 1884. The accident seems to have been caused by her stepping inadvertently into a hole about four inches deep in the street crossing. In support of her claim, Dr. Jas. W. Ranney testified that she had concussion of the spinal column; that before the accident she was an unusually strong, hardy woman; and that now it was only a question of time when she would die from the effects of her injuries.

The principal witness examined for the defence was Dr. N. M. Shaffer, who said he had examined the plaintiff, and could say positively that she had no disease or injury of the spine. There were no soft spots in the marrow, as Dr. Ranney testified. The spinal column was in its normal condition. Her only trouble was hysteria. Falling forward as she did, it was impossible for concussion of the spine to result. If the woman would collect her will power she could get up and walk as well as anybody.

From our appreciation of the skill and integrity of Dr. Shaffer, and from certain sidelights thrown upon this case by points in its history which have no medical interest, as well as from our acquaintance with a number of suits for damages to which this one does not appear unlike, we are inclined to the belief that the city of New York does right to interpose every legal obstacle to the claim for damages made by this woman. It is true that a physician testifies that she has been seriously injured, and that positive testimony usually carries more weight than negative. But it by no means follows because one or a number of medical men testify that an injury, inappreciable to the senses of the laity, is present in a given case, that it is so. Unfortunately, there are some medical men who, in the hope of gain, will become surprisingly acute in discerning such injuries; and there are more, who are so moved by sympathy, and so credulous of the assertions of their patients—and especially of their women patients—that it is not hard to get them to corroborate what the latter say, and to supply them with terms which prove impressive to a jury, for symptoms or conditions which are common and innocent enough.

Such things are happening every day; and it behooves those who have the opportunity to express the sentiment of the medical profession, to protest against a wicked, or an amiable, prostitution of its reputation to the uses of designing persons. As a class, medical men have the deepest sympathy for suffering, and are always ready to assist in securing redress for an injury. But they have no interest in robbing corporations on account of injuries which have never taken place; and they cannot be too careful to avoid becoming abettors of any scheme which may do an injustice if it succeeds, or bring shame upon them if it fails.

TETANUS FROM USE OF THE STOMACH-TUBE.

The *New Yorker Med. Presse*, December, 1887, brings to us, through several intermediate channels, the report of an interesting case of death following speedily the use of an œsophageal or stomach-tube. The patient was a man forty-eight years old, who had been treated seven years before for stricture of the pylorus. At the time when he came again under treatment, he was suffering with flatulence, pain, progressive weakness, and frothy vomit. His stomach was found to be dilated. It was decided to wash out his stomach, and a tube was passed down his œsophagus. Hardly was this down, when he became faint, and the instrument had to be removed. Two hours afterward his jaws became stiff, he could not open his mouth, his arms became rigid, pronated and flexed, and his thumbs were flexed in his palms. He retained his consciousness; but was in a profuse sweat. Gradually all the muscles of his limbs and trunk became rigid; his temperature rose to 113°, and he died cyanosed.

At the autopsy, the diagnosis of stricture of the pylorus and dilatation of the stomach was confirmed, and no lesion of the mucous membrane of the œsophagus could be found.

The presumption is that this was a case of tetanus, caused by the mere impression of the operation. It is analagous to a few other recorded cases in which tetanus occurred, for which there seems to be no explanation, except that it was largely due to a mental impression. A number of these cases are precisely like certain cases of so-called hydrophobia, in which no material injury, no infection can be supposed to have given rise to the symptoms, and in which the phenomena are only explicable by the assumption that they were due to a pure psychosis.

This assumption does not make the *rationale* of such occurrences clear; but it may prevent false notions in regard to their etiology. It may, therefore, be useful to call attention to this new illustration of the possible effect of a trifling operation which makes a great impression on the mind of the patient, in order to point out what may be at the same time a source of great danger and an occasion of false theories in regard to morbid manifestations. In the case mentioned above, perhaps no foresight could have prevented the catastrophe, and certainly none of the recently announced theories of the etiology of tetanus can explain it.

SUB-PUBIC LITHOTOMY.

At a meeting of Berlin surgeons, Nov. 7, 1887, LANGENBUCH delivered a lecture on what he called "Sectio alta Sub-pubica." Impressed with the dangers and inconveniences of perenial lithotomy, Langenbuch has for some years practiced, and advocated the merits of, suprapubic lithotomy. But even this has its dangers, namely, the formation of prevesical phlegmon, if the sutures placed in the bladder do not hold; and the inconvenience of obstruction of the catheter sometimes placed in the urethra for the purpose of drainage. Langenbuch therefore proposes opening the bladder, to remove a stone, by means of an incision between the root of the penis and the pubic bone. This incision should be cross-shaped, and should be made so as to not to implicate the corpus cavernosum or the vena dorsalis of the penis. On reaching the bladder, the venus plexus at its neck should be pushed aside. To give room, he suggests that the lower portion of the pubic bone may be chiselled away. After this—or without it—the bladder is to be incised; and then it can be thoroughly explored, and any foreign body in it can be removed. If this be found impracticable, Langenbuch advises proceeding at once to open the bladder above the pubes in the usual manner of suprapubic lithotomy. For drainage he proposes making a counter incision through the perineum, in which a drainage tube is to be placed, while another occupies the sub-pubic wound. In this way, the urethra is not used at all for drainage.

This proposition of Langenbuch he has never put into practice, and it is founded upon purely theoretical opinions. It includes two principal points: the first, approaching the bladder immediately below the arch of the pubes; the second, making a counter

opening through the perineum for drainage. Neither of these is likely to meet with general acceptance. As long ago as 1750, Pallucci proposed making a counter opening in the perineum for drainage after suprapubic lithotomy; and for about fifty years after 1758, Frére Côsme practiced it with results which satisfied him, and which were excellent for that time.

The sub-pubic route to the bladder may have some merit; although it is not easy to say wherein it adds to the chances of success which are offered by a properly chosen operation for stone by way of the perineum or by way of the hypogastrium.

ALBUMINOUS PERIOSTITIS.

Not long since, Prof. Ollier, of Lyons, whose special studies in diseases of the bones and joints have been so extended and so thorough as to entitle his opinions to the greatest weight, described as a special form of periostitis that in which the affection is not accompanied by the formation of pus, but simply of a watery, albuminous, sometimes of a yellowish fluid, in which fat globules are present. This form of periostitis is sufficiently common; and certain German surgeons soon published observations and opinions corroborative of those of Ollier in regard to its features and its peculiar character.

But it is questionable if it be an advantage to attempt to set apart as a peculiar form of disease—except for conciseness of description—one which has a common origin and a common history with other varieties of a well-recognized class. It is not surprising, therefore, to find so accomplished a surgeon as Prof. Roser, of Marburg, protesting (*Centralblatt für Chirurgie*, Dec. 10, 1887), against the distinction made by Ollier, and endorsed by Riedinger, and Schlange in Germany, in regard to so-called "periostitis albuminosa." In the brief paper referred to, Roser shows that this form of periostitis has been fully recognized and well described before Ollier discussed it, and that it is so far from being a special disease that he himself has found it in the left tibia of a patient who had an ordinary osteo-myelitic abscess in his right tibia.

We share the opinions of Roser in this matter, and think it a mistake to attempt to make a special class of cases of periostitis in which there is no pus formation—except, as stated above, for mere convenience of description. For it may be desirable to have a short term, by which to express the difference between periostitis with pus-formation and that with the accumulation of a watery, albuminous, and sometimes fatty fluid beneath the periosteum. If this be all that is implied by the expression "periostitis albuminosa," we cannot see any harm in it.

VARICOSE VEINS IN THE TONGUE.

At the meeting of the Berlin Medical Society, November 23, 1887, Dr. Lazarus presented a patient who had a dilatation of the veins of the dorsum of the tongue. The patient had applied for treatment on account of expectoration of blood. There were no indications of lung disease in his physical condition, or from his family history. In examining his pharynx, Dr. Lazarus discovered at the base of the tongue, on the left side, far back, a bluish swelling, about half an inch wide, and extending to and upon the epiglottis. The patient said he had had, years before, a varicocele; but at the present time he had no evidence of it, or of any other varicose veins than those in the tongue. Treatment addressed to the pharyngitis granulosa, which the patient had, was successful; but the varicose veins remained unaffected by it.

The interest in this case is connected with the danger of hemorrhage from sudden rupture of the varicosity; the difficulty which might be experienced in checking it; and the possibility of an error as to its source.

NUTRIENT ENEMATA.

Prof. Ewald, of Berlin, has recently made some careful experiments with different nutrient enemata (*Deutsche Med. Woch.*, Dec. 1, 1887), and has found that enemata of eggs were of decided service; and that they were as efficient and satisfactory without being peptonized as when they were subjected to this process.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

DOCTOR AND PATIENT. By S. WEIR MITCHELL, M.D., LL.D., Harv., Member of the United States National Academy of Medicine, etc. 8vo, pp. 177. Philadelphia: J. B. Lippincott Company, 1888. Price, $1.50.

It would be impossible to do justice to this unusually interesting and very instructive book in the space we can spare for our reviews. Those who are familiar with the author's style need not be told that he has a peculiar faculty for putting facts which many people observe in a way which few people could emulate. He seems to take each reader into a sort of confidential and familiar relation, and to talk to him as a personal acquaintance. In this way he has succeeded, in the book before us, in putting what he was tempted, he says, to call "Lay Sermons" in a shape which is at the farthest possible removed from sermonizing. As we glance over its pages we find it hard to refrain from quoting some of his wise and kindly instructions or suggestions. But we will not anticipate the pleasure of our readers when they have the book in their own hands.

REPORT OF THE SURGEON GENERAL OF THE ARMY, for the fiscal year ending June 30, 1887. 8vo, pp. 107. Paper. Washington: Government Printing Office, 1887.

Most of this report is made up of matters of special interest to medical officers in the army. But there are a number of matters of interest, from the standpoint of hygiene and the diseases of certain localities, to medical men in general practice. We note, also, the fact that the number of medical officers in the army who are permanently disabled is becoming a cause of embarrassment to the efficiency of the medical department, and that the Surgeon General, Dr. Moore, urgently recommends that an increase of twenty assistant surgeons be authorized.

HEALTH LESSONS. By JEROME WALKER, M.D., Lecturer on Hygiene at the Long Island College Hospital, etc. Small 8vo, pp. 194. New York: D. Appleton & Company, 1887.

Dr. Walker has essayed a difficult task—to write a book that shall embody scientific truth in regard to matters of life and health in such a way as to interest and instruct children. He has succeeded quite well. The teachings of his book are sound and his style is interesting, most of the illustrations are very good, some of them are beautiful. A few are of questionable taste; on the whole we think this the best book of the kind which has been subjected to our criticism.

FEVER NURSING, DESIGNED FOR THE USE OF PROFESSIONAL AND OTHER NURSES, ETC. By J. C. WILSON, A.M., M.D., Visiting Physician to the Philadelphia Hospital, etc. 8vo, pp. viii, 210. Philadelphia: J. B. Lippincott Company, 1888. Price, $1.00.

This is an admirable book by one perfectly competent, from his experience in practice and in teaching, to prepare it. It is the substance of lectures delivered to the class of nurses in training at the Philadelphia Hospital, and embodies clear and useful instructions for the management of fever patients. These instructions are, however, applicable to almost any form of disease, excepting surgical cases. Recent experience prompts the suggestion that it would not be amiss to add to them some upon certain homely subjects, such as the ministrations of the nurse in giving food and in assisting in the acts of urination and defecation. These ministrations, if properly carried out, may be a great alleviation of the miseries of a severe illness; while, if carelessly or ignorantly performed, they may materially increase these miseries.

This by way of suggestion. As it stands the book before us can be recommended in the strongest terms to nurses and to physicians. It is well written and very handsomely printed; and its moderate price brings it within the means of all who need it.

A LABORATORY MANUAL OF CHEMISTRY, MEDICAL AND PHARMACEUTICAL, Etc. By OSCAR OLDBERG, Pharm. D., Professor of Pharmacy in the Illinois College of Pharmacy, and JOHN H. LONG, Sc.D., Professor of Chemistry in the Chicago Medical College. 8vo, pp. 435. Illustrated (with five plates).

The object of this work is to provide lessons for laboratory work in chemistry with especial reference to the preparations used in medicine in the United States. The execution of this plan is well carried out, the processes being simply and clearly described and confined to those having the most important bearing upon pharmacy and the practice of medicine. In the part of the book devoted to analytic chemistry we note that Moore's test for sugar in urine is not given. This, although by no means an exact test, is, within certain limits, a useful and satisfactory one. Here also we find album*en* (in urine), where we think album*in* a preferable term.

Throughout the book the quantities are given in parts, or in measures of the metric system. This is an almost universal custom in works on chemistry. We think it would be no disadvantage if the corresponding quantities in Troy measure had been placed with those of the metric system.

As a whole we believe this book to be worthy of strong recommendation; and we heartly congratulate the authors and the publishers upon its contents and appearance.

Pamphlet Notices.

Clinical Report of Surgical Cases Operated upon by Prof. A. C. Bernays. Reported by Dr. W. V. Kingsbury. From the *International Synopsis of Medicine and Surgery*. 8 pp.

Comparison Between the Surgical Diseases of the White and Colored Races. By Louis McLane Tiffany, M.D. From the *Transactions of the American Surgical Association*, 1887. 4 pp.

An Experimental Study of the Effects of Puncture of the Heart in Cases of Chloroform Narcosis. By B. A. Watson, A.M., M.D. From the *Transactions of the American Surgical Association*, 1887. 37 pp.

Rubella (Rötheln; German Measles) with a Report of 150 cases. By J. P. Crozer Griffith, M.D. From the *Medical Record*, July 2 and 9, 1887. 36 pp.

—Dr. Kingsbury's Report contains brief accounts of the more important operations of Prof. Bernays at the Surgical Clinic of the St. Louis College of Physicians and Surgeons, from September 22 to October 22, 1887. These include a resection of a rib,

extirpation of the tongue, laparotomy, Porro's operation (mother died in few days; child living), gastrostomy, nephrectomy (patient died in 18 hours).

—Dr. Tiffany has studied the comparative effects and results of surgical affections in the white and colored races during a period of thirty-four months, and in 4930 patients. Abscesses, spinal caries, keloid, inflammatory phimosis are relatively more common among negroes than among whites; congenital defects are more rare among negroes than among whites; suppurative troubles and diseases affecting the lymphatic system are more common among negroes than among whites; negroes bear surgical injuries and operations better than whites.

These interesting conclusions of Dr. Tiffany suggest, as he says, further study. His pamphlet is illustrated with a fine phototype of a remarkable case of keloid in a negro.

—Dr. Watson presents a very thorough and valuable study of the effect of puncture of the heart upon animals subjected to chloroform narcosis. He describes in detail the results of sixty experiments; forty of which were made on animals suffering from complicated traumatic injuries, and forty on animals healthy and uninjured. He concludes that puncture of the heart, especially of the right ventricle stimulates its muscular contractions; and that this is of advantage in dangerous chloroform narcosis; especially if a certain amount of blood is also abstracted with the puncture.

The views of Dr. Watson met with some criticism from his fellows in the Surgical Association; but they deserve careful consideration and perhaps a more favorable acceptation than they received when first announced. As a contribution to our knowledge of the phenomena of the hearts movements under mechanical stimulation they are of great value.

—Dr. Griffith's pamphlet contains the most complete summary of the history of rubella (or German measles) of which we have knowledge. It also contains a very clear synopsis of its symptoms and course; and—less than six lines in regard to its treatment. This is summed up in the injunction to give a light diet; to keep the patient in bed for a few days, if there is fever, and in the house for a week. Chilling of the body is to be avoided, and severe symptoms or complications are to be treated as they develop. Dr. Griffith says, that rubella is usually a disease of no danger whatever. This is no doubt true; but one of the saddest cases of which we have ever known was that of a child of a physician in Philadelphia, which had what was diagnosticated as German measles, followed by indubitable evidences of pus formation in various parts of the body, including the brain, with extreme and persistent contractures and long continued imbecility. Such a fact as this should be borne in mind in judging of the possible effects of what may seem like a trifling malady.

—The care of croup.—Dr. H. R. Wharton lectured, Dec. 22, 1887, before the Nurses' Training School, in the amphitheatre of the University Hospital, on the duties of nurses in the care of cases of croup, before and after the operation of tracheotomy. He showed his audience the different appliances used in the treatment of that disease, and the method of cleansing the tube which is inserted in the windpipe after the operation.

Correspondence.

Twisted Terms.

Ed. Med. and Surg. Reporter:

Sir:—Your "humor" column in the Reporter induces me to tell you what a good woman said to me three years ago. I am sure it will be appreciated by the doctors. She said, "I am so sorry for Mrs. ——, she has been a confirmed infidel for five years, not able to sit up at all. She had a sore, and the cantereen set in, and the doctors held a meeting over her, and thought her limb would have to be amphorated." And in a certain town in Orleans County, New York, an ignorant man given to struggling with big words, said to me, "No, I haven't been what you might call *well* in some considerable time. I consulted Dr. ——, and he told me my trouble was a stoppage in the seekerative ducat of the liver." I told him that, although I am a minister and not a doctor, I believed that particular ailment of the liver to be generally fatal unless attended to in its incipient stages!

Yours truly, J. W. Sanborn.

Lockport, N. Y.

Chewing and Swallowing Glass.

Ed. Med. and Surg. Reporter:

Sir:—At the risk of being considered over-credulous or easily deceived, I write you in regard to a novel case that recently came under my notice.

A negro man, named Bill Jones, 39 years old, recently visited this State. He says he has been eating glass since he was two years old. He has never been sick enough to require the attention of a physician. I saw him eat part of a lamp chimney while on exhibition, and took him to my office and saw him perform the same feat two or three times. Most people will not believe he eats the glass, but I know it is no trick of legerdemain.

If I am not mistaken, it has been the opinion of the profession, as well as of the laity, that powdered glass was sure to cause death if swallowed in any large quantity. This negro says he has eaten as many as five large lamp chimneys without stopping. He chews the glass about as fine as one would ice. He says he discharges it from his bowels in the same state as when swallowed. He never suffers from any pain in his stomach or bowels. Have you, or any of your readers, ever seen or heard of such a case?

Please don't say that it is simply a sleight-of-hand performance. *I know he eats the glass.*

Yours, truly, B. B. GRACY, M.D.

Smyrna, Tenn., Dec. 26, 1887.

[There can be no doubt that certain public performers have chewed and swallowed glass with apparent impunity, and we have no doubt that Dr. Gracy's observation is correct. If glass be chewed small enough, it would probably be a fairly safe, though not a very nutritious, article of food. Most people would find it impossible to chew the glass without cutting their mouths. But, if they succeeded in this step, there is no reason why it should not pass through the bowels. —EDITOR OF THE REPORTER.]

Experience with Antifebrin.

ED. MED. AND SURG. REPORTER:

Sir:—Not seeing much written, and seeing some inquiry about antifebrin, I have concluded to give the readers of the REPORTER my experience.

Case 1.—Wm. D., age 18, an epileptic, was just getting over an attack which left him with a terrible headache. I gave him four fifteen-grain capsules, one to be taken every three or four hours until he was easy. He took one at noon, and one at 4 P. M. His head was easy at 6 P. M., and he slept well. The next morning he had a slight headache, and took one capsule. He reported himself as cured that evening.

Case 2.—Mr. V. D., age 57; first stage of typhoid fever, with temp. 104°, pulse 80, and severe frontal headache. It was my first visit, and he lived near Wm. D. I had not been in the house long when he asked me if I had any of those capsules for headache that I gave to Wm. D. I said I had, and gave him a ten-grain capsule, which eased his head, made him sweat terribly, reduced his fever two degrees, and brought his pulse down to 56. I thought it was the antifebrin which reduced his pulse, but I found it was not, by leaving it off. I continued to give him ten-grain capsules every afternoon; gave one every three hours, and only one day did he have to take the third dose. He made a good recovery.

Case 3.—Mary B., age 19, has tabes mesenterica, with headache, dry skin, quick pulse, etc. I give her eight to ten grains of antifebrin nearly every afternoon, and never have to give the third dose.

I find in antifebrin a medicine which will relieve nearly every kind of headache, and reduce the temperature when there is fever. In the majority of the persons to whom I have given it, it has produced sleep more natural than that caused by opium or chloral.

Yours truly, S. R. HUMSTON, M.D.

Smithville, Ind., Dec. 30, 1887.

A Warm Friend.

ED. MED. AND SURG. REPORTER:

Sir:—For the past seventeen years the REPORTER has never failed to visit my office once a week, and we are not only old friends, but also fast friends. For these years it has been my constant companion. It has visited with me many hundred tedious and wearisome cases, and in the long hours of the sick room, it has been my instructor and assistant. In many difficult, dangerous and obscure cases, it has been to me a very present help in time of need, conveying to me the knowledge of cases of the same character that some other brother in the profession had had, and how he managed them. Though wearied with the press of business, and worried with its anxieties, I have always found time to read its plain, condensed, practical and often brilliant articles. I have been in the active practice of medicine for more than a quarter of a century, and have been all of that time a constant student; yet I feel the need of a good live journal as much to-day as I ever did. And I would urge my younger brethren in the profession to secure some good journal—preferably a weekly, and *my preference is the* REPORTER—and never let its subscription lapse while in practice. No physician can do justice to his patients or to himself without such aid.

Having been a reader of the REPORTER under its three managements, it may not be presumptious in me to state my idea of its value. The REPORTER has always been good—worth many times its subscription price. To be frank I think you have in many ways improved its usefulness—that its society, clinical and case reports are better, more practical in character and contain more of the resources of the profession. I also admire the spirit of conciliation manifested—the live and let live theory. Life is too short for bickerings; science is cosmopolitan; all of our resources should be freely divided with our brethren and the world.

Keep on the safe ground of well-attested experience in practice; give us all of the latest and best, and success for the journal in the future as in the past will be assured.

Yours truly, J. B. HATTON, M.D.,

Secretary U. S. Board of Examining Surgeons,

Red Oak, Iowa, Dec. 26, 1887.

Notes and Comments.

The Use of Ligatures on the Limbs During Surgical Operations.

In the *N. Y. Medical Journal*, December 17, 1887, Dr. L. M. Sweetnam, of Toronto, recommends the employment of ligatures in surgical operations in order to secure more rapid anæsthesia, with the employment of a smaller quantity of the anæsthetic. This procedure has been employed by other surgeons, and Dr. Sweetnam does not claim originality for it. The advantages of this method are stated to be:

1. But little time is lost in securing complete anæsthesia, and but little in waiting for returning consciousness before leaving the patient after the completion of the operation.

2. If the bands are applied ten or twelve minutes before the first incision is made, the operation will be a comparatively bloodless one, and the surgeon works more rapidly and more comfortably than he would if the hemorrhage were more severe.

3. Saving of blood to the patient.

4. If collapse appears to threaten the life of the patient, the removal of one or more of the ligatures can be relied upon to bring about a prompt reaction.

5. There is less vomiting and distress after the use of the anæsthetic.

6. The small amount of ether or chloroform used, from an economical point of view.

7. Fewer ligatures and compression forceps are required to control the bleeding.

8. Less embarrassment of lungs and kidneys, and lessened risk of serious injury to these organs if diseased.

Care is to be observed in employing this method where there is a history of purpura. The author also states that while the constriction may be kept up for two hours with perfect safety, it is well to keep the limbs wrapped in blankets, so as to prevent serious loss of heat.

Erysipelas in an Infant Three Weeks Old; Recovery.

T. B. Greenley, M.D., in a communication to the *South-Western Medical Gazette*, says that on October 10, 1887, he was called to see an infant three weeks old suffering from erysipelas. The disease first manifested itself the day before, and affected the labia. The parts were very much tumefied and indurated, which led him to regard it as a case of forming abscess. At this time the disease had not extended from its original site. The temperature was 102°. On October 12, the inflammation was extending towards the right hip, and erysipelas was then diagnosed; the temperature was then 102.5°. The tumefaction of the labia increased. Solution of acetate of lead was used locally; the other treatment consisting of chalk and bismuth was continued.

By October 15, the inflammation had extended upwards as high as the navel on the right side, and as low down as the knees on both sides. The temperature, however, had fallen to 101.5°. The lead solution was changed for hyposulphite of soda, for fear of lead poisoning from absorption. The labia were still greatly tumefied and hard, but with no sign of pus. The treatment with milk punch, which was begun two days before, was continued, with the addition of a small quantity of morphia, to procure quietude.

The next day the disease ceased to extend upward, but still continued to extend downwards.

By the 19th, the disease had reached the feet, which were greatly tumefied. The labia were not quite so much swollen and slightly less hard. The child rested and nursed well; the temperature was 100°. The same treatment was continued.

On October 23, the inflammation had disappeared from the feet, and the patient was convalescent.

Treatment of Middle Ear Complications of Scarlet Fever.

Dr. Samuel Theobald stated before the Clinical Society of Maryland, at its meeting on December 4, 1887, that in his experience he had obtained very little effect from the use of the tincture of iodine, or the oleate of mercury locally; but had found that atropia sulphate, grains four to ʒj, would give great relief. He usually drops five or six drops in the ear and keeps the child quiet for several minutes. He thinks he has seen cases of such inflammation cut short by this method of treatment. In addition to atropia he now intends to use cocaine. He does not think that external applications accomplish much. Atropia gives almost instant relief from pain, and if used early enough will often prevent destruction of the drum membrane.

At the same meeting Dr. Hiram Woods remarked, that cases of purulent otitis from scarlet fever are attended with more complete deafness than otitis from other causes, and that they are very hard to cure. The cavity of the middle ear is usually filled with granulations. Atropia gives almost instant relief if the drum is not ruptured;

but when purulent otitis exists and the drum is still intact, the best treatment is to puncture it and let the inflammatory material out.

Dr. I. E. Atkinson said, that the frequency with which the hearing may be saved depends upon the time of interference, and, that if the drum is punctured when bulging takes place, many cases of hearing may be restored. Objections to the idea of not performing tracheotomy in these cases, do not have the slightest force. If any lives were shown to have been saved by it, then tracheotomy should be practiced; but one hundred per cent. die. In diphtheria it should be performed because a certain number of lives are saved by it.

Necrosis of Temporal Bone and Rupture of Internal Carotid.

This case is related by Sutphen, in *Archives of Otology*, vol. xv, No. 4. A man of twenty-five years of age, who had suffered with an abscess in his middle ear from his fourth year, was suddenly seized with pain and right-sided facial paralysis, and then with paralysis of the left half of the body. Shortly after this, pains came on in the right side of the head, followed by giddiness and nausea. The abscess then discharged, and the symptoms for a while abated. Three months later he became worse, hæmorrhage occurred from the ear, and he died. *Post-mortem* examination revealed a sequestrum in the deep parts of the temporal bone, which had eroded the wall of the internal carotid as it entered the skull. The cavity, formed by caries of the temporal bone, was connected through the internal auditory meatus with an abscess of the overlying half of the cerebellum. Above and in front of this was found the remains of an earlier abscess, which was thought by the author to account for the symptoms of paralysis which had been noticed, which had disappeared, following the escape of pus from the fistulous opening under the ear.—*Centralblatt für Chirurgie*, October 22, 1887.

Treatment of Gleet.

The *Quarterly Therapeutic Review*, Oct. 1, 1887, says that Dr. Fred. A. A. Smith, Cheltenham, asserts that some years ago a captain in the army consulted him about a gleet he had had for a long time. Nothing seemed to do him any good; at the same time he was anything but a temperate man, and practically was a very bad subject for treatment. He ordered him an ordinary alum lotion to be used as an injection, and for medicine, acid nit. dil., ♏xv; dec. cinchonæ flav., f℥j, t. d. Returning home from his club in the evening, he took by mistake a dose of the alum lotion, and used the acid mixture as an injection. The consequence was that he suffered great pain for over half an hour, but cured his gleet. Noting this, Dr. Smith tried on his next case, acid nit. dil., ♏v; dec. cinchonæ flav., f℥j, as an injection, t. d., and found his patient got rapidly well, and has since used this treatment in several cases with very happy results.

Multiple Ulcers of the Cornea following Exposure to Electric Light.

Mr. T. Phillips, Clinical Assistant to Moorfield's Eye Hospital, reports in the *Lancet*, December 3, 1887, the case of an electrician, twenty-four years old, who, while engaged in making observations of a very powerful electric arc, removed the usual protection from the eyes in order to make a better examination. His eyes were thus exposed to the action of the light for about four minutes. Nothing abnormal was noticed following this exposure until about four hours subsequently, when, on awakening from a sound sleep, he suffered from acute pain in and about the eyes, great intolerance of light, and inability to sleep. The patient's own statement was, "I am stone blind." Five days after the accident, he was still suffering from acute pain and dread of light, which was overcome sufficiently to permit an examination by a ten per cent. solution of cocaine. The anterior surfaces of both corneæ were affected. The right was dotted all over with small definite ulcers. The left had six such ulcers arranged in pairs of three rows disposed vertically. The appearance of these ulcers was similar to that presented by the corneal ulceration which occurs in states of perverted innervation of the eye. The ophthalmoscope revealed nothing abnormal.

The eyes were bathed with boric acid lotion, and a solution of cocaine and atropine applied night and morning. In the meantime both eyes were closed with pads smeared with boric acid ointment. The patient was well in two weeks.

Ointment for Syphilitic Psoriasis.

Mauriac recommends for the syphilitic psoriasis which affects the palms of the hands and soles of the feet, the following ointment:

Oil of cade,	
Mercurial ointment.....	āā ℥ij
Vaseline.....	℥j

Mix.

NEWS ITEMS.

—Dr. W. Joseph Hearn, of Philadelphia, has removed to No. 1120 Walnut street.

—A dentist in Pittsburg, who pulled a sound tooth by mistake, has been sued by the man from whom it was taken for $200,000. When it is considered that a whole set of A 1 teeth can be had for less than one hundred dollars, the plaintiff does seem a little exorbitant.

—The New York correspondent of the Philadelphia *Ledger* says that the East river bridge has become to a certain extent a health resort. Physicians prescribe for dyspeptic patients, or for those who suffer with lack of appetite, a walk back and forth, once in twenty-four hours; and at certain hours of the day there is abundant evidence that the prescription is acted upon.

—There are about fifty small-pox patients in the pest house in San Francisco at the present time, and several have died, though the malady has generally been of a mild type. It is claimed the first case was brought there by a China steamer about three months ago. Four Chinamen are said to have died on the voyage, but, as the ship's physician failed to make a report of the fact, the ship was allowed to land her passengers without remaining in quarantine.

—A writer in the *Westminster Review* on "Physic in the Far East" states that in Japanese medical history women were early instructed in the art. They were, with other doctors, admitted to the concurrent practice of charms and incantations, and in 723 female professors were appointed to teach medicine to their sex. At present women are allowed to practice there, and two Japanese ladies who had obtained diplomas in Western medicine should not find any but the medical prejudice in their way.

—What may fairly be called an epidemic of sore throat has been prevalent in Edinburgh for some weeks. The sore throat is peculiar. There is much redness of the palate, fauces and tonsils, with a tendency to the formation of gray patches. The appearance is thus suggestive of the scarlatina throat, and the mode of onset simulates that of scarlet fever. It is, however, unaccompanied by an exanthem, and the febrile symptoms abate rapidly. Suspicion of infection through milk has been aroused, and observations are being carried out on the subject.—*Brit. Med. Journal*, Dec. 24, 1887.

—To one of his physicians, Dr. Timann, the German Emperor recently expressed the wish that he might find it convenient to take an apartment nearer the palace. On his frank reply that his means did not allow him to live in the most expensive quarter of the city, the Emperor quietly caused an apartment to be hired and furnished at his own expense, within three minutes' walk from the palace, so that he is now able to call him at a moment's bidding, an electric telegraph having been specially arranged to connect the Emperor's study with that of Doctor Timann.—*N. Y. Tribune*, Jan. 2, 1888.

—The London Temperance Hospital has been established fourteen years. In that time alcoholic stimulants have been resorted to in not more than five cases, and in these instances the results have proved no more successful than where the remedies ordinarily used in the hospital were employed. Up to the present time over 30,000 patients have been under treatment, more than 12,000 of whom were to a greater or less degree addicted to drink. Many of those seeing the good effect of this treatment have become total abstainers. In fatal cases there were fully one-fifth more deaths among non-abstainers than among teetotalers.

—There has been an overturning in the Medical Staff of the County Hospital of Chicago, due, it would appear, to political machination. The staff is now constituted as follows:

Dr. Chr. Fenger, Dr. D. A. K. Steele, Dr. A. J. Baxter, Dr. Albert B. Strong, Dr. A. E. Hoadley, Dr. W. T. Belfield, Dr. Truman W. Miller, surgeons; Dr. O. J. Price, Dr. A. J. Coey, Dr. Melins, Dr. A. C. Cotton, Dr. John A. Robinson, Dr. J. P. Ross, Dr. P. J. Rowan and Dr. J. R. Brandt, physicians; Dr. Denslow Lewis, Dr. C. W. Earle, Dr. Charles Henrotin and Dr. John Guerin, gynæcologists. Pathologist, Dr. J. E. Colburn.

—On Friday, December 30, a meeting was held at the College of Physicians and Surgeons in New York city, for the purpose of organizing an American Physiological Association. The association has for its object the promotion of physiological research and of social intercourse among the physiologists of the country. The association will meet as a section of the Medical Congress every three years. The meeting was presided over by Dr. S. Weir Mitchell, and many prominent physiologists from all parts of the country were present. A constitution was adopted, and Prof. H. P. Bowditch, of the Harvard Medical School, was elected president, and Prof. H. N. Martin, of Johns Hopkins University, secretary and treasurer.

HUMOR.

A CORRESPONDENT asks "if it is really true that Job was troubled with boils?" There can be no doubt that he was if he had them.

A STRANGE THING: Jones—Strange thing, Mirandy; every time you draw a breath somebody dies. Mrs. Jones: Well, I ain't going to stop breathing on that account.

DR. BIGBILL—You may thank your stars, sir, that physicians in these days don't bleed patients afflicted with your malady, as they used to. Patient (dubiously)—I'm not so sure that they don't, doctor.

AN ENGLISH JUDGE is said to have laid it down from the bench in 1882 (see *Times* report, October 4 of that year) that "liars may be divided into three classes: Liars, great liars, scientific witnesses."

SMITH—HELLO, JONES! you don't look very well this morning. Jones—And I don't feel as I look. Got up in the middle of the night to take some pills, and swallowed four collar buttons before I found out the mistake.

NO CONFIDENCE IN THAT DOCTOR.—Wife (to third husband)—"If you feel so unwell, John, I think we had better send for my old family physician." Third husband (somewhat hastily)—"No, my dear, I would prefer to send for some one else."

"HELLO, NOBSON, you're not looking well." Nobson—"I am under the weather. Have had to leave off smoking, too." Johnson—"That's bad, that's bad." Nobson—"But that isn't the worst of it. I am dreadfully afraid that leaving off smoking is going to do me good."

OBITUARY.

BALFOUR STEWART, LL.D., F.R.S.

Professor Balfour Stewart was educated at the Universities of St. Andrews and Edinburgh. He had been in turn Director of the Kew Observatory, Secretary of the Meteorological Committee, and Professor of Natural Philosophy in Owen's College. He was fifty-nine years old.

DR. CHARLES T. WIDNEY.

Dr. Charles T. Widney died in Los Angeles, California, on November 6, 1887, at the age of forty-five years. He was born in Kentucky; educated at the University of Louisville; served during the war as surgeon in the southern army; afterward was for a few years in private practice, but spent most of his professional life in charge of private asylums for the cure of the alcohol and the opium habits, in which special field he was eminently successful.

SIR GEORGE BURROWS.

Sir George Burrows, formerly Physician to the St. Bartholomew's Hospital, and Physician in Ordinary to the Queen, died in London recently, at the age of eighty-six.

CHARLES LANGER, M.D.

Dr. Charles Langer, Professor of Anatomy and Director of the Anatomical Institution in the Vienna Faculty of Medicine, died on December 8, 1887, of chronic disease of the lungs.

CHARLES G. POMEROY, M.D.

Charles G. Pomeroy, M.D., died in Newark, Wayne county, N. Y., on the 14th day of December, 1887, in the 71st year of his age. Dr. Pomeroy was one of the most distinguished members of the profession in central New York. He was a permanent member of the American Medical Association, and of the State Society; a member, and one of the founders, of the New York State Medical Association; Ex-President of the Medical Association of Central New York, and of his County Society. As a citizen he stood high, and had the confidence of the community in which he had resided nearly fifty years. D. C.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Jan. 1, 1888, to Jan. 7, 1888:

Major P. J. A. Cleary, Surgeon, granted leave of absence for one month. S. O. 138, Dept. Ariz., Dec. 25, 1887.

Capt. R. G. Ebert, Assistant Surgeon, ordered from Fort Custer, Mont., to Fort Pemlina, D. T. S. O. 301, A. G. O., Dec. 30, 1887.

Capt. A. H. Appel, Assistant Surgeon, granted leave of absence for twenty days. S. O. 1, Dept. Mo., Jan. 3, 1888.

First Lieutenant C. B. Ewing, Assistant Surgeon, granted one months' leave. S. O. 137, Dept. Mo., Dec. 27, 1887.

First Lieutenant Wm. B. Banister, Assistant Surgeon, ordered from Fort Lowell, Ariz., to Fort Wingate, N. M. S. O. 3, A. G. O., Jan. 5, 1888.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Jan. 7, 1888:

R. D. Murray, Surgeon, on being relieved at Ship Island, Miss., to proceed to Key West, Florida, and assume charge of the Service. Jan. 4, 1888.

S. C. Devan, Passed Assistant Surgeon, relieved from duty at Port Townsend, W. T., to assume charge of the Sapelo Quarantine. Jan. 5, 1888.

A. H. Glennan, Passed Assistant Surgeon, relieved from duty at Key West, Florida, to assume charge of the Service at Port Townsend, W. T. Jan. 5, 1888.

P. M. Carrington, Assistant Surgeon, promoted and appointed Passed Assistant Surgeon from Jan. 20, 1888. Jan. 7, 1888.

ERCILDOWNE.

A Private Medical Hospital for Mental and Nervous Diseases.

Situated at Wissinoming, in the suburbs of Philadelphia, eleven miles from Broad Street Station, on the New York Division of the Pennsylvania Railroad, and within two minutes walk of the station. Commodious in structure, richly furnished, having large, airy rooms, thoroughly ventilated and heated and cheerful sun parlors front and rear. It covers twenty-nine acres of lawn and gardens, and is free from malaria. Each case receives the attention and study given to private practice, and physicians can continue as consultants in cases committed by them.

DENTAL IRRITATION AS A FACTOR IN THE CAUSATION OF EPILEPSY.[1]

BY ALBERT P. BRUBAKER, M.D.,
PHILADELPHIA, PA.

In all the wide divergence of view as regards the nature of epilepsy there is a general consensus of opinion that its essential feature is of the character of an explosive discharge from the higher nerve-centres, the nerve-force thus liberated bearing down upon the centrifugal distributions of the motor nerve-tracks with such an excess of energy that inco-ordination of movement reaches the stage of convulsion and spasm. Owing to the periodicity of the convulsive seizures, it has been assumed that in individuals predisposed to epileptic attacks the higher nerve-centres are in a state of high tension, of unstable equilibrium, and that it only requires a stimulus of a definite quantity or intensity to excite the explosive discharge.

Writers have generally laid it down as an established fact that the majority of the cases of epilepsy are idiopathic, without definite causation, and due solely to heredity; but it can scarcely be doubted that these cases are properly so classed only as regards the predisposition, and that in them all a morbid action, even though slight in amount, is necessary to call forth the nervous discharge. The morbid process may be centrally located and beyond the reach of investigation, or it may be peripherically located and excite the convulsion in a purely reflex manner. It is fully conceded by all that injuries to nerves, diseases of the ear, intestinal worms, phimosis, uterine troubles, etc., are all not uncommon peripheral causes resulting in epileptic attacks.

The question has been raised, however, as to whether a convulsive attack due to a peripheral irritation can be regarded as a true epilepsy, and whether it is not to be regarded rather as of a hysterical character. Without attempting to pass judgment upon this subject, it will suffice to quote the recent views of a very competent authority upon nervous diseases, Prof. H. C. Wood. In commenting upon the convulsion due to a peripheral irritation, he says, "It is almost invariably epileptiform in its general symptoms, and may conform exactly to the typical epileptic attack;" and, while admitting that many of these reflex convulsions partake largely of the hysterical character, he further says, "There are, on the other hand, convulsions which conform to the epileptic type, and which are the result of an organic peripheral irritation."[2]

A remarkable feature of the epileptic convulsion is its periodicity. Now, it is proved beyond question that the higher nerve-centres of the brain act not only as inciting, but also as inhibitory centres to those of a lower level. They are at once reservoirs of nerve-force and regulators of its dispensation. If, therefore, a morbid process at the periphery continuously attack, through nervous intermediation, these higher nerve-centres, it follows that these in time must have their resisting power overcome at intervals and at successively higher levels, until a final one is reached, when control is no longer possible. The unremitting irritation having at last overcome the resisting power of the highest nerve-centres, their energy is suddenly liberated and the organism is flooded with waves of uncontrollable centrifugal energy, until

[1] Read before the Philadelphia Neurological Society, December 19, 1887.

[2] "Nervous Diseases and their Diagnosis."

exhaustion brings about a temporary equilibrium.

The object of this paper is to direct the attention of physicians to a cause of epilepsy which has not hitherto been estimated at its full value, inasmuch as in none of the standard works upon neurology is the subject even alluded to, viz., pathological state of the dental structures. That dental inflammations and disorders are more often provocative of epileptic seizures than is commonly supposed appears quite certain from the following cases, and also from the character of the cause and its effect. Many reasons might be given why dental disorders are peculiarly adapted to call forth this periodical discharge, and why these disorders are habitually overlooked by the physician, but they need not be detailed here. As exemplifying these phenomena, some interesting and instructive cases are adduced.

The following case occurred in the clinical service of Dr. Wharton Sinkler, at the Orthopædic Hospital and Infirmary for Nervous Diseases, to whose kindness I am indebted for the privilege of recording it:

Case I.—Mary L., aged 9, was brought to the hospital in October, 1886, with a history of epilepsy dating from May of the same year. The convulsive attacks first made their appearance on the afternoon of the same day that the child had had three teeth extracted on account of repeated attacks of toothache. One decayed tooth, however, was left remaining in the lower jaw. Previous to coming to the hospital, the epileptic attacks occurred two and three times a week. From all that could be learned from the mother, the symptoms were those of a typical epilepsy. There was no neurotic history in the family. She was placed upon from three to five drops of the fluid extract of cannabis indica for two weeks, during which period she had twelve attacks. The bromide of sodium was then given for two weeks, during which she had sixteen attacks. From November 1 to March 1, 1887, she continued taking the bromides alone, in combination, and, finally, in conjunction with the infusion of digitalis. During the four months of steady treatment she had forty seizures. About the 1st of March the mother made the remark that the child was always extremely restless at night; that she would lie awake for hours complaining of toothache; and even when asleep she would continually grind her lower teeth against the upper teeth. Examination of the mouth revealed a carious and inflamed condition of a molar tooth in the lower jaw on the left side.

From the history of the case, and the possibility that the irritation arising from the diseased tooth might be the exciting cause of the attack, it was concluded to have the tooth removed. This was done under the influence of nitrous oxide gas. The night following the child rested much better, and from that time forward her sleep became natural, her appetite improved, and her general health became decidedly better. From the last week in February until the present time (December 19, 1887) she has not had a single symptom of an epileptic attack.

That a dental irritation should be capable of exciting an epileptic condition does not appear at all strange when it is fully comprehended how numerous are the recorded cases of ocular, aural, visceral, muscular, and nervous disorders which have been caused by the irritation arising from the pathological conditions of the teeth and associated structures.

The interest aroused by the result of the preceding case led to an examination of medical literature for reports of similar cases. I find that no less than sixteen cases, entirely and immediately cured by the removal of an irritating tooth, have been recorded by different observers, and which are here arranged in chronological order. It is not supposed that this collection embraces all the recorded cases, but it is hoped that it will elicit references to many others, and, what is more important, the reporting of many new cases.

The injurious effects of diseased teeth, and the irritation arising from them, in the production of many general diseases, did not escape the acute mind of Dr. Rush. In a paper published in his collected works[1] he records the following:

Case II.—"Some time in the year 1801 I was consulted by the father of a young gentleman in Baltimore who had been afflicted with epilepsy. I inquired into the state of his teeth, and was informed that several of them in his upper jaw were much decayed. I directed them to be extracted, and advised him afterwards to lose a few ounces of blood at any time when he felt the premonitory symptoms of a recurrence of the fits. He followed my advice, in consequence of which I had lately the pleasure of hearing from his brother that he was perfectly cured."

Dr. Ashburner published,[2] in 1834, a number of remarkable cases of hysteria, spasms, convulsions, etc., due to diseased conditions

[1] Enquiries and Observations, vol. i, p. 199.

[2] On Dentition and some Coincident Disorders, p. 98.

of the teeth. Among others was the following case of epilepsy:

Case III.—A young lady of highly nervous temperament was attacked with epilepsy in the eighth month of her first pregnancy. She had two attacks before her labor, which was a very favorable one. Seven months afterwards the fits reappeared, and occurred two and three times a week. Various methods of treatment were resorted to without success. For a while the intervals between the attacks were somewhat longer, and for a while they appeared twice daily. An examination of the mouth revealed seven carious teeth, which were at once removed. Three wisdom teeth were prevented from erupting on account of a cartilaginous condition of the gums. These obstacles were removed. The epileptic fits at once ceased, and after several years they had not returned.

Case IV.—Albrecht relates[3] the case of a boy, aged 12 years, who for a period of six months suffered daily with general convulsive attacks. Just preceding the attack there was severe pain in the temporal region. No cause could be assigned for the seizures. Treatment was without avail. Examination of the mouth revealed an overcrowded condition of the teeth, which were in addition unusually large. After removal of some of the teeth the convulsions subsided, and in a short time entirely disappeared.

Case V.—Dr. Tomes publishes[4] the following: "A lad, a farm-laborer from Windsor, was admitted into the hospital for epilepsy. The usual remedies were tried for six weeks without effect. His mouth was then examined, and the molar teeth of the lower jaw were found to be much decayed, and of some of these only the fangs remained. He did not complain of pain in the diseased teeth or in the jaw. The decayed teeth were, however, removed, and the fangs of each were found to be enlarged and bulbous from exostosis. During the eighteen months that succeeded the removal of the diseased teeth he had not suffered from a single fit, though for many weeks previous to the operation he had two or three per day."

Case VI.—Dr. Baly records[5] the history of a case of epilepsy from dental irritation, occurring in a man, aged 45. The patient was an employée in the Millbank Penitentiary; was of good physique; in good health, and had never suffered from vertigo, headache, or any form of nervous trouble. In the latter part of October, 1850, he began to suffer from toothache. On November 4, the tooth was examined by the medical officer, but on account of its carious condition and deficient light it was not extracted. Nitric acid, however, was applied, which gave the patient relief. On the 6th the muscles of the right side of the face began to twitch. The muscular spasms lasted four or five minutes, and occurred three or four times a day. "At these times, when the twitchings had reached a certain degree of intensity, the jaw became locked, and he lost the power of speech; but he had no pain in the head, giddiness, or sense of stupor. The paroxysm of spasm in the muscles of the right side of the face and jaws recurred the next day, and on the following day, the fourth after the examination by Mr. Chatfield (the medical officer), the twitchings became more violent, and his jaw locked. He had the sensation of all his teeth falling out, and then lost consciousness. A strong convulsive fit ensued, which lasted half an hour; the same night he had a second fit." These attacks were described as presenting all the features of an epilepsy. A third attack occurred before morning. The next day the tooth was extracted, together with a small piece of bone attached to the root.

For one month the patient was perfectly well, but on the 7th of December, in the middle of the day, he again experienced the spasmodic twitchings, and at the same time became conscious of the existence of something protruding from his jaw; with his fingers he removed a piece of dead bone. In the evening of the same day the spasmodic contractions of the face occurred several times. On the night of December 8, he awoke with a spasm in the cheek, and upon getting out of bed fell upon the floor unconscious; a general convulsive fit followed, during which there was foaming from the nose and mouth. At 6 A. M. a second fit followed, more violent than the first, and lasted five minutes. In the intervals of these attacks there was considerable uneasiness and confusion of mind. The next night he suffered a return of the fit. Examination of the mouth revealed a swollen and tumid condition of the gum, but there was no discernible source of irritation. The patient was placed on calomel to prevent further mischief to the deeper-lying structures around the diseased tooth-socket. He remained well until February 22, when he had, for the space of ten minutes, the same premonitory twitchings in the muscles of the face, but no real fit. A small piece of dead bone was extracted from the gum, after which the old

[3] Casper's *Wochenscrift*, 1837, p. 125.
[4] System of Dental Surgery.
[5] *London Med. Gazette*, xlviii, p. 534–540.

wound healed, and the patient entirely recovered.

In 1857, Dr. Sieveking read[1] before the Royal Medical and Chirurgical Society a paper entitled "An Analysis of Fifty-two Cases of Epilepsy." In the discussion that ensued Sir Charles Locock said he had noticed the omission in the paper of a very common cause of epilepsy, viz., dentition. He could not agree with Dr. Ashburner that all cases of the disease could be cured by the removal of the teeth; but he had certainly seen the affection cured in more than one instance by removing overcrowded teeth.

Case VII.—Dr. Ramskill publishes[2] the following: "A boy, 13 years old, has had frequent attacks of epilepsy for the last eighteen months. Latterly, his mother noticed that some days he rubs his left cheek, complaining of face-ache, after which the fit follows. On examining the mouth, there is to be seen a molar tooth considerably decayed, with a swollen gum around it and partly growing over into the cavity; it is not very tender to the touch, and the examination does not give rise to toothache. On questioning, I find the sensation which the boy experiences before the fit does not seem to be one of pain, but rather of indefinite uneasiness. He always has a fit the night this comes on. He never felt it during the day; it is always about seven or eight o'clock. I desired the mother to have the tooth extracted, and ordered a simple saline, with ¼ grain of belladonna, to be taken twice daily. This was in June. The tooth was extracted next day. I saw this boy once a fortnight from that time for four months, but he had no recurrence of the fits. In this case I believe an unfelt aura commenced about the gum surrounding the tooth, and was not recognized till some degree of inflammation arose, and thus a modification of pain became associated with the aura and directed attention to it."

Case VIII.—Trousseau relates[3] the case of a patient, a young notary's clerk, under the care of Dr. Foville, who had been subject to monthly attacks of epilepsy for several years. Many remedies had been tried in vain. Dr. Foville suggested the extraction of some carious teeth which ached constantly. The suggestion was acted upon, and from that day the fits disappeared.

Case IX.—Dr. Garrett related the following case before the Suffolk District Medical Society, and was reported by Dr. Page:[4] "A man, aged 40 to 50 years, had suffered with his teeth for years; these had been extracted and artificial ones substituted. He became paralyzed in the muscles of his face and tongue. There was a peculiar drawing of the mouth, from which the aura epileptica came just previous to the fit; the tongue was inclined to fall back within the mouth; he was fearful of swallowing it. In investigating the case Dr. Garrett removed the false teeth, and found the soldering discolored; he went back to his dentist, had a rubber plate made, and had no further attacks of epilepsy; the paralysis gradually subsided."

Case X.—W. H. Waite reports[5] the case of a young woman, aged 18, who consulted him for treatment for a carious condition of the incisor and canine teeth of the upper and lower jaws. The teeth had been diseased for four years, and were very sensitive. For three years the patient had been subject to epileptic attacks, which were at first quite slight, but had gradually increased in severity. After removal of the diseased teeth and filling of others, the epileptic fits entirely ceased. After some months the fits returned, attended with sharp, shooting pains in the alveolus. Examination showed that several other teeth had become decayed. These were removed, and from that time on there was no recurrence of the epilepsy, and the patient increased in health and weight.

Case XI.—Dr. Nathan Field reports[6] the case of a boy, about 5 years old, who was suddenly seized with an epileptic fit. In two weeks he had a second attack, which passed away after a few minutes. In the course of the next ten days it was estimated that the boy had a thousand convulsions, occurring every few minutes. No cause could be assigned. It was finally observed that before the appearance of the convulsion there was a twitching of the muscles of the left side of the face. Finally, after a severe convulsion, while the child was unconscious, he drew up his upper lip, when it was observed that the canine tooth had, instead of causing absorption of the deciduous tooth, pushed it outward through the alveolus, the gum, and into the lip. The tooth was removed, and in less than an hour the convulsions subsided and never appeared again.

Case XII.—Mr. Canton related[7] the history of the following case: A strong, healthy boy, aged 19, who had become the subject of epileptic fits, applied to Mr. Canton for treat-

ment. As the cause of the fits could not be ascertained, it occurred to him that they might be due to the eruption of a wisdom tooth. The gum was freely incised, and the crown of the tooth laid bare. From that time the fits never returned.

Case XIII.—Mr. Henry Moon related[1] the following case: "The patient, a girl, aged 21, was brought as an out-patient to Dr. Fagge, at Guy's Hospital, and he, finding that her teeth were in a very bad state, sent her to Mr. Moon. She had suffered from fits since she was fourteen, and lately they had become so frequent as to reduce her almost to the condition of imbecility. On examining her mouth, a third molar was found in process of eruption; this he lanced freely. Some carious teeth were extracted and others were filled. Treatment by the bromides of potassium was ordered at the same time. The result was that the fits entirely ceased from the day of her first visit to the hospital. The girl recovered her intellect, and although she was kept under observation for several months, she had no return of the fits."

Case XIV.—Dr. Schwartzkopf reported[2] the following case in the *Deutsche Monatschrift für Zahnheilkunde*, 1886: "A man, aged 27, suffered severe pain in the right upper central incisor, which was carious, and consulted a dentist, who filled it. Soon after this a swelling appeared in the hard palate, where an opening formed. The patient was now easy, but the tooth continued loose and tender when touched. The fistula also remained patent and discharging. Ten days after the tooth was filled the patient had an epileptic attack, and these recurred at gradually shorter intervals, until, at the end of eighteen months, they occurred several times a week. During this time the patient was treated with bromides, atropine, etc., but without results. The tooth was then extracted, the fistula healed, and the fits ceased, and at the time of reporting the patient had remained free from them for four years."

The two following cases are reported[3] by Dr. Liebert:

Case XV.—Emil S., aged 25, in good health and with no neurotic tendency, began to suffer with attacks of vertigo in February, 1883. These attacks lasted several minutes, after which the patient appeared perfectly well. On one occasion, however, the vertigo was so severe that he was compelled to sit down to keep from falling. On one occasion he lost consciousness. By April 25 the attacks had greatly increased in severity. On this day he had such a severe epileptic attack that Dr. Liebert was called in. The patient had been lying on the floor for fifteen minutes wholly unconscious, and most of the muscles of the body in a state of tonic contraction; the pupils were of medium width and insensible to light; there was also a fresh wound of the tongue. After careful inquiry, it was learned that just previous to the attacks the patient experienced a peculiar tickling or crawling sensation in the tongue, an inability to speak words distinctly, and some involuntary movements of the tongue. Immediately after there followed the giddiness, the fall, unconsciousness, etc. Despite large doses of the bromides, the attacks increased in frequency and severity. Finally, in June, he began to suffer with toothache. Examination of the mouth revealed several carious teeth, one of which was very sensitive to percussion. This was extracted, and from that moment all peculiar sensations and motions of the tongue ceased, and there has not been in the past two years a single epileptic seizure. This patient had in the four months several hundred attacks of vertigo and eighteen or twenty typical epileptic convulsions.

Case XVI.—Young man, aged 35, cabinet-maker. Began having epileptic attacks on February 3, 1862, which came on almost daily and with increasing severity. On March 5 he had twenty-three seizures. With the exception of toothache he had never been sick. Repeated inquiries elicited the information that from December, 1861, the use of his tongue was for some seconds, or even minutes, frequently rendered difficult, and this fact was coupled with a certain feeling of illness or vertigo. In the attack of February 3, 1862, these symptoms were exceptionally severe, the tongue being drawn to the right side and executing spasmodic movements. Immediately thereafter he became unconscious and fell to the floor in convulsions. The tongue symptoms were usually premonitory of the frequent subsequent attacks. Owing to the fact that the aura appeared to be connected with the mouth, it was determined to seek for the cause in that locality. As he had had toothache occasionally, several carious teeth were removed. The patient at once declared that he felt an unwonted freedom from a former oppressive feeling, and that he believed he would have no more of the seizures. His conjecture was correct, for he remained free

from them from that time forth. This patient had epileptoid vertigo for three or four months, and severe epileptic attacks for thirty-eight days.

STERILITY, ESPECIALLY IN SYRIAN WOMEN.

BY S. LOUISE WEINTRAUB, M.D.,
PHILADELPHIA.

During my three years' practice in Damascus, Syria, two-thirds of my patients came to me for sterility. The disgrace which in olden times caused Rachel to cry out to Jacob, "Give me children or I die," is still felt by Eastern women. A fruitful cause, it seems to me, is the early marriage common among them. Among the Moslems, whose doctrines have a very degrading and debasing effect on womanhood, girls are married when from eight to fourteen years old. Girls after eighteen being considered "old maids" are asked in marriage only by widowers of forty or over, and as second wives to men already married.

Amongst the Greek and Roman Catholic Syrians, from twelve to sixteen is the common age for marriage. A difference in age between the sexes of from ten to fifteen years is considered proper both by them and by Moslems. The Jews likewise marry early, but the sexes are more nearly of an age. A young wife is preferred, as she more readily conforms to the household of her father-in-law. The ancient patriarchal system still continues. The sons bring home their wives to their father's house as in the olden time. Each is allowed a room for himself and his family, and here they sleep, father, mother and children, side by side, upon beds made up for the night upon the floor, these beds being rolled up and put away in the day-time. But all the families eat together at the same table, as a rule.

The mother is the ruler and *chaperone* of the son's wives, she knowing where each one goes or what she does. This is her highest position, and when she has attained this place her home is assured as long as her sons live, it making no difference, or only very little, when her husband dies. But with the sterile woman it is different. Her condition often is a cause for divorce amongst Moslems and Jews, or the reason why a Moslem marries a second wife. If the first wife is very rich or beautiful, or much beloved, she would insist on a divorce if a second wife were brought to the house. To meet the case, a white slave is often bought, who is really a wife to the man, but occupies the position of a slave and obeys the whims of the wife. The children of this slave take the rank of the father, however, and are often much beloved by the woman who has not been blessed with children. As there is no such remedy as divorce amongst the Greeks and Roman Catholics, sterility frequently gives rise to cruel and unkind treatment from the husband.

Among Syrians the sterile woman experiences great hardships, and often fails to keep her husband true to her. She must bear his constant reproaches that she is useless, and often hear the complaining question, "Why should I save money when I have no one to inherit it?" The secluded life of a sterile wife often lacks the interest, love and occupation which children bring to the mother and a certain degree of liberty which she enjoys; while the men miss the highest honor that can be paid to them—to be called father of Salime, or whatever the first-born son's name may be. The honor of fatherhood is so great in the East that a Moslem will be sometimes called by the name of an imaginary son. The loss of this honor makes the men extremely bitter towards their wives, who are always considered to be the one at fault.

This condition of things causes women to to do everything that lies in their power in hope of relief, and they often endure great suffering in consequence. They go from midwife to midwife in their faint hope, and often become invalids for life, if they are not carried off by a sharp peritonitis or metritis. The shrines of various holy persons reputed to have helped others are visited, Moslem women tieing a little piece of rag on the window of one of the shrines, so that the holy one should remember them and grant them their prayer. I have often had to remove pledgets of some pungent-smelling drug, whose name I did not know, from my patients who came to me after having been to these various midwives. The patient frequently suffers intense pain from the treatment to which she is subjected, and the vulva and vagina become greatly swollen and inflamed; peritonitis, or cellulitis even, often resulting.

Some of the remedies used are cayenne pepper, onions, melted butter, garlic, raw meat, spices, mastich, mixtures of various raw drugs, dried flowers and plants of various reputation. Some of these are taken by the mouth, but most of them are applied *per vaginam*. A kind of sound is also used, which has been described to me as made of bone and being sharp-pointed. I have heard of one woman who underwent treatment with this

instrument, and died after a day or two, the uterus probably being perforated. There are certain drugs reputed among Moslems to produce boys, and are consequently frequently resorted to.

There are many Bedouin Gipsy women who go crying through the streets "medicine for sterility," fortunes told, etc., and many a desperate woman catches at this straw, only showing how great their disgrace is felt to be. A few have even overcome the custom of years, and have allowed a medical man to examine them. Any one who knows the belief of Moslems, and the great disgrace this is felt to be, will understand the significance of such a concession.

A frequent cause of sterility is the remains of a bad cellulitis or metritis, the result of some heroic treatment. Sterility often follows the birth of a child, and is due to the lack of proper care after parturition. Or when the patient has taken cold and a slight inflammation of the genital organs has followed, this has been greatly increased by injudicious applications made by a midwife, the result being a metritis or cellulitis.

In my practice, when I found upon examination that a woman who was sterile had no visible or serious hindrance to conception, one of my first steps in undertaking her treatment was to have the husband sent to a doctor, who would examine the spermatic fluid and send me a written record of the result. If that was as it ought to be, I would proceed with the woman's case. Frequently a small and undeveloped uterus seemed to be the only cause of sterility. In these cases I would use dilatation by sea-tangle tents. My mode of proceeding would be to order the patient to let me know the day that the menstrual period was finished. That day she went to the bath, and the next I would go to her house and introduce as large a tent as possible.

The following cases illustrate my practice:

Case I.—Greek, of the wealthy class, was married when fifteen years old, and is now over twenty-seven years of age. She has been under the treatment of numerous noted physicians of Beirut and Damascus, but never was pregnant. Her husband is a third son; his brothers and sisters have large families. Her own brother has also a large family, but one sister is sterile.

On examination I found her uterus one and a half inches in length, very small, but movable. Her menses were regular. There was no inflammation of the genitals, except a slight irritation of vagina. I treated her a few times, and then, on the sixth day of her menstrual period, I dilated the os uteri with a No. 1 sea-tangle tent. I found much difficulty in introducing it; but kept it in place with pledgets of cotton dipped in glycerine.

The tent was removed after eight hours, the patient not having moved all this time, but having lain perfectly quiet upon her back. That night there was connection, and the patient remained in bed three or four days. The husband was also under treatment. She did not become pregnant until the second menstrual period, when she conceived, and afterwards was delivered in due time of a fine healthy boy.

Case II.—Greek, aged eighteen years, married at the age of thirteen; has never been pregnant during the five years of her married life; menses regular and painless. Her husband was well developed and strong. In the section of the city in which she lived, the women are not allowed any liberty, and cannot go out until after they bear their first child. So this poor little woman was not allowed to go even to the bath or to church, except a few times. In all these five long years, her small dreary house was almost a prison—for the houses are very differently built in Syria from the way they are built in America. On examination I found her uterus very small, but movable and not inflamed. Her entire appearance was very girlish—even more so than is general amongst Eastern women. At the same time after the commencement of the menstrual period as was chosen in the former case, a tent was introduced, and this was followed by the same restriction to bed. She stayed in bed three days, and I did not allow her during the entire month to do any work. She became pregnant that same month and at full term gave birth to a nice little girl. I could give the histories of other similar cases; but these show some points of my line of treatment.

I found that I was successful when the patient had not been tampered with much by midwives, and if, at the same time, the husband had tonic treatment if he were not robust. Another point I found to be important was to introduce the tent directly after the menstrual period, before any connection had taken place, and to have connection accomplished immediately after removal of the tent. I also advised that connection should not take place within two or three days of the next menstrual period. If the menstrual flow did not appear then, I forbade any further intercourse until the uterus had risen out of the pelvis.

I think it extremely important that a microscopic examination of the spermatic fluid should be made before any effort of the kind I have described is made. For, in not a few cases under my observation, the men proved to be at fault, and were beyond hope of help, nothing being the matter with the women. The following case shows the advisability of observing the precaution:

Case III.—A young Bedouin woman came to me from a distance of two or three days' journey. Her husband was a Sheik and had had three other wives, but had had no children by any of them. She was very bright, and said she had often been told, if she would just step aside from the straight road, she could soon become pregnant. But in the free desert life amongst the higher Bedouins, virtue is the rule; and she would not do so. Examination showed her uterus and appendages to be in perfect condition. But on examination the Sheik was found to be entirely at fault. In such a case treatment with a tent might have been injurious and certainly would have been useless.

In my experience I have found that but little could be done for cases of old cellulitis or metritis. Treatment in cases of recent cellulitis was more hopeful, and even old cases were sometimes relieved.

Many of my successful cases I was unable to follow up, because the women were afraid I would expect some remuneration. I was frequently puzzled by not finding any visible cause for sterility in either my patient or her husband.

I had no results from the use of the sound, the introduction of which, two or three times a week, is advised in some text-books for the treatment of sterility. I also found that mischief might result from frequent introduction of the sound after intercourse between husband and wife. Women will become pregnant after long years of sterility. So I never used the sound except immediately after a period. The rule and custom in the East is that connection shall never take place until after the woman has been to the bath. Usually the eighth day is the one observed.

I have had no opportunity to test what effect electricity might have in such cases as we are considering. The frequent success of the treatment with tents was due, I think, to the fact that dilatation overcome the stricture of the internal os, and frequently started up a retarded development of the body of the uterus. Again, hardness of the cervix—a frequent cause of sterility—was often overcome by this treatment.

The fact that I never observed real or serious inflammation as a result of dilatation with tents was due, I think, to my never introducing a tent if the slightest tenderness of the uterus was present, or if the introduction of the sound was unusually painful. I also watched my patient carefully, never allowing her to get up if the slightest tenderness existed, and not permitting intercourse if the tenderness persisted for more than a day.

Though various plans have been suggested for treatment of sterility, it has seemed to me that there is very little positive knowledge on this subject. Of course, I treated inflammations with the regular remedies in use. But for many of my patients I was unable to do anything of the sort, for they did not seem to need it, and it did not help them. I should be very glad to have other ideas in regard to the treatment of sterility, on which so much of the weal or woe of Syrian women depends; for any physician, being among them, cannot help having his or her strongest sympathies aroused by the misery and unhappiness which this condition entails.[1]

721 South Twenty-first Street.

REMOVAL OF THE UTERINE APPENDAGES FOR DISEASE IN WHICH PAIN IS A PROMINENT SYMPTOM.[2]

BY HOWARD A. KELLY, M.D.,
PHILADELPHIA.

According to the request of the directors, that I should prepare a paper briefly discussing the operation for removal of the ovaries and Fallopian tubes in those cases in which pain is a prominent factor, and accepted as one of the indications, I have thus, although under great pressure from other work, gladly conformed to their wish, and here bring before my coworkers in other fields some of the fruits of

[1] As I am concluding this article, a letter reaches me from Jerusalem—which is ten days' journey by land from Damascus—asking my advice and treatment for sterility. This letter was originally sent to Damascus, the writer not knowing that I had left that city. The fact that it was sent there shows that a report of the success of my treatment had reached that distance. The anxiety of the Syrian women to become mothers is so great that they will undergo the fatigue of long journeys, or any inconvenience or loss which may be necessary, in order that they may consult a physician who has a reputation in this matter.

[2] A paper read before the Philadelphia County Medical Society, at a stated meeting, December 28, 1887.

my labors and thought in this unsettled territory of ovarian disease. In the brief time allowed I cannot read references and quotations, and will speak rather from my personal experience and of the results in cases, some of which have been traced for several years, and now may be referred to as permanently cured or improved. Only by *permanency* can any proper estimate be placed upon the value of reported results, and while successful cases are being reported in large numbers daily, within a few days or weeks of the operation, but little has been said of the condition in which the patients found themselves after one, two, and three years.

My opinion relative to the class of cases suitable for operation, to the results to be expected from operation, and as to the operation upon neurotic cases pure and simple, conforms closely to that expressed by Professor Hegar in his monograph, *Der Zusammenhang der Geschlechtskrankheiten mit nervösen Leiden und die Castration bei Neurosen.* Nearly as I agree with Professor Hegar, I differ very widely from many other "authorities," so called, in this much-contested field. Still more widely do I differ from many views which have gained currency in the profession at large, as to the indications for and against operation, the certainty and the permanency and the value of the results obtained.

The convenience of assuming the symptom *pain* as a characteristic factor of the group of heterogeneous cases we are about to consider is at once evident. With this symptom patients usually apply, and ask for nothing except that their *pain* be relieved, and under present modes of treatment and indifferent specialization in medicine, in cases even of marked disease of a minor character, the patient often goes through a protracted course of treatment in which nothing is distinct outside of the subjective elements of the case. *Pain* alone drives most patients to consent to adopt whatever means the surgeon may propose as remedial. By thus emphasizing this subjective feature, and also by the natural history of the diseases, we exclude all those cases from our study in which *size* is a characteristic.

We have left then a great group of mixed pelvic diseases lesser in size, but not in the elements of danger: causing more suffering, with greater certainty undermining the health, and in no sense less important than the large fibroid, dermoid, or ovarian cystoma, unless we measure disease by the tape measure. "What the eye sees not the heart grieves not," is true of those who find it so difficult to realize the great hourly danger in which their patients may be living, in whom nothing may be apparent to the eye, and but little to an unpractised touch.

Common among the diseases referred to are: ovaries enlarged by cirrhosis; ovaries with extensive follicular degeneration; hemorrhagic ovaries; ovaries containing pus sacs; neuralgic ovaries; ovaries involved in a withering of the pelvic peritoneum with the tubes, and tubo-ovarian disease, with co-existing hydro-, pyo-, or hæmato-salpinx. These three names, however, signify not the disease itself, but an accident of the disease, which may be absent and the disease still exist. Pyo-salpinx is a misnomer, as the disease may exist in all its essentials, and the tube contain no pus, but the ovary may be converted into a large pus sac. In my experience, abscess of the ovary with a tube much thickened, gelatinous and friable on section, but containing no pus, is quite as frequent as a large tube sealed and distended with pus attached to a small ovary simply enveloped in inflammatory products. I believe that the entrance of the septic material into the ovary takes place through a ruptured follicle. In a case upon which I operated one year ago, my patient married a man suffering from gonorrhœa; she experienced no difficulty until the time of her first menstruation, when she was seized with violent pains and remained an invalid ever after, until I removed the mass.

Hydro-salpinx is more commonly associated with some mild non-septic pelvic inflammation which has resulted in sealing the fimbria, and hydro-salpinx results. It may, by distention of the tube, cause pain; but the morbid process usually long antedates the formation of any tumor. If this were not the case, the rational procedure would be unquestionably slitting open the tube on its dorsum, careful removal of the fluid, and an attempt to establish a pervious uterine opening by passing a small canula into the uterus, which could be removed later per vaginam. The disease, however, lies back of this, and the fluid formed is but one of its sequelæ. Here at once is a reason why operations upon tubes thus enlarged are not always and at once successful in curing the patient of all disability.

I am at present making daily visits to a patient operated upon in the spring, from whom a large hydro-salpinx was removed, along with the ovaries and tube of the opposite side. Her uterus and structures lateral to it are now free from all sign of disease, but there still linger low down in the pelvis foci of inflammation in the cellular tissue,

which, although objectively small, cause a disproportionate distress to the patient. The operation was here an imperatively necessary step, but still only one step on the road to cure.

Hydro-salpinx is at times associated with anomalies in the development of the individual. Thus I operated last week in Chicago on a married woman, about thirty-eight, who had been a great sufferer ever since puberty. I found an infantile uterus, two very small white ovaries, that on the left side being no larger than, and of the shape of, my thumb-nail, while vaulted over it was a large tube distended by several ounces of watery fluid. The indication in this case was not the size of the tube, but the establishment of the menopause to relieve painful ovulation. In pyo-salpinx, on the other hand, the starting point and focus of the disease are often the intensely poisonous contents of the tube, which involve surrounding structures by successive invasions; and here, were it practicable, the disease might often be cured by removing the tube alone, leaving the ovary; but of such a conservatism I do not approve, as the ovary without its duct is useless, even dangerous.

Of hemato-salpinx I will not speak further than to say emphatically that I do not believe that all these cases are extra-uterine pregnancies, and to draw attention to the fact that the contents of the sac may be as acridly poisonous as that of pyo-salpinx, and should receive the same extreme care in removal.

It would be better if pain, *per se*, were never considered a sufficient indication for operation; or, at the worst, only those cases operated upon in which the most prolonged and painstaking care had failed to relieve, and where the intensity of the suffering must always seriously interfere with the capacity of the patient to enjoy life. We here meet the neurologist on common ground, and it would be better for all such cases if they first underwent a prolonged treatment at the hands of these specialists. A host of cases of neuralgic ovaries which have been sacrificed by the gynecologist would thus have been cured, and many cases which have been operated upon and not relieved would at least have been spared the ordeal of operation, and the too frequent reproach thus be spared the gynecologist, that he recommended the removal of a woman's ovaries, but she declined, and a nerve specialist afterward cured her; and, to make the reflection worse, she has since borne a child. I have a case in which a friend considered removal of the ovaries would be necessary some two years ago, so great were the patient's sufferings, but with the gradual compensating hypertrophy of an insufficient mitrally diseased heart, she has improved, and is now six months pregnant. A prominent factor in causing pelvic distress, aggravated at the menstrual period, is, I am now convinced, large varicose veins in the broad ligaments. I think I can almost always recognize these cases now by the character of the pain, the facies of the patient and a peculiar sense of boggy fulness to the vaginal finger. Constipation seems to be one factor in the causation, but while relieving constipation helps the condition, I have not found that it cures any case of long standing. Sequelæ of pregnancy may cause it. My experience as an operator leads me to reject removal of tubes and ovaries as in any way assisting a cure. In one case sent me by one of the most prominent neurologists in the country last spring, the patient is but little improved, although one of the veins tied and cut off was a half centimetre in diameter. As nothing else seems to do more than mitigate this condition, I propose yet to open the abdomen and simply tie the distended tortuous veins at either end, aspirating then, if necessary, and if the patient is no better she will at least be no worse off.

One class still remains, usually classed among the neuralgic cases, and this class Dr. S. Weir Mitchell has happily defined, giving appropriate form to an idea which I have for some time entertained—they are those cases in which the expectancy and concentration of the attention on a normal function leads it to simulate disease in the expression of pain. These cases, if operated upon, rarely reflect credit upon the operator, and should ever be considered more in the province of the neurologist than of the gynecologist. I have never operated on a case of this sort, and never expect to. I have been speaking somewhat briefly of cases in which pain is the only local manifestation of disease. There is a small group of cases in which general nervous phenomena of an aggravated character seem after a time to subside into a local disease. I have in mind a case of salaam convulsions which lasted many months, was followed by severe neuralgic pains in various parts of the body, then by severe pelvic pains, and at the operation small cystic ovaries were discovered, and the patient promptly and completely cured by their removal. It is impossible, however, for any but a specialist to distinguish with certainty between those cases in which there are no

manifest gross changes in these organs and the cases about to be described, in which the trained touch can with certainty and exactitude determine the nature and extent of such changes. I know by my own progress in this matter how impossible it is for any but the touch which is daily exercising, improving and correcting its inferences, to come to any definite conclusions in this matter, as to the size and position of the ovary and tube, whether cystic, how much enlarged, and if adherent. All these and other questions are but matters of daily practice for years to decide in all cases.

One of these cases I show you to-night was treated by more than thirty physicians, and had received almost as many differing opinions, no one recognizing the true nature of her disease, which I had the satisfaction of determining at once to be abscess of the ovary, the instant my finger swept over the vault of the vagina. Another patient was treated for fourteen years, and her physician, who lived in central New York State, recognizing some similar symptoms in a case upon which he saw me operating at my private hospital, sent her down to me, and she is now very much in the improved condition of the patient you have just seen. Here, also, I removed ovaries greatly enlarged by old encysted abscesses.

Briefly, then, as to the status of this operation—the removal of *diseased* appendages, small in size, but in which pain is a prominent symptom—as a scientific operation:

1. It is scientific, because it deals with *diseased organs*.

2. It does more than almost any other single surgical procedure in relieving a large number of cases whose sufferings have been almost unbearable.

3. In *properly* selected cases the percentage of recoveries is over ninety-five per cent., and improving, and the percentage of cures equally large.

4. Unless we adopt the yard-stick as our measure of disease, the indications for operative interference are often more urgent than in the case of most cystomata coming under our observation.

And, lastly, all the steps of the operation, the technique of the procedure, have now been so widely appreciated, that it may be described as a *safe* operation.

In marked contrast to this statement might be cited the case of Sir Spencer Wells, in the days when this operation was in its infancy. We can here readily discover one reason why Sir Spencer has always been so bitterly opposed to operations of this class. He operated upon a woman fifty years of age, for the purpose of inducing the menopause. In opening the abdomen the intestine was cut, the ovaries were not completely removed, and the mesentery prolapsed from the wound, and a bad hernia followed. Such was the result of an imperfect technique in the hands of one who in the generation past did more for abdominal surgery than any other man of his time.

Of all the questions relative to this work, that of *results* most nearly concerns us. As to the *immediate* results, life or death, I will speak of that under the title of Danger of the Operation. I refer here to the result relative to the *curing of the disease* in those cases which have recovered from operation. A satisfactory inquiry upon this heading will depend entirely upon the standard which we erect beforehand, by which to test our results. The brilliant results occasionally following this operation, and the many sanguine reports of operations in which the patients are reported to have been the most wretched of all sufferers, and by the abdominal section to have been at once and forever relieved from all pain, to have recovered health at once, and been able to return often to duties of a very laborious nature, have conspired to bring about such a state of professional opinion, that cases which cannot show these results are thrown back upon the operator as failures.

There was at one time, when this operation was dangerous, as in that cited by Sir Spencer Wells above, some reason for this opprobrium, and the results gained were measured by the danger passed through, and often found inadequate; but with the great diminution of the danger, the whole status of the question has altered. My own standard is this:

Are the organs diseased? Will their removal cure the patient entirely, or will it relieve a large part of the suffering and at least make life more bearable? A result *absolutely* good is always to be desired; but a result *relatively* good is something to be very thankful for, and grasped in many cases. Not only the general profession, but gynecologists themselves are apt to place all hope upon the operation, like a throw of dice, and to forget that it is often more rational to handle the cases from the beginning of their treatment to the end, in such a manner that the operation is viewed by doctor and patient as simply a *step*, at times the only one, again the most important step, or occasionally but one in the flight, in the treatment and progress toward cure.

Cases often require after-treatment, and

some of my patients have only left me entirely well after weeks more of work. My operation removed, it is true, the focus of the disease, without which I could never have made any progress, but my after-treatment dealt with the disease products which may have been accumulating for years, the embers, ever freshly kindling so long as the diseased tube and ovary remain, but now readily yielding to treatment. In other cases, I have been actually obliged to deal with disease of my own creating, for in three cases I have treated the women for cellulitic deposits formed, I believe, around the ligature at the stump.

Since my return from Europe, on Sept. 7, 1887, I have operated upon fourteen cases of abdominal tumors, including hysterectomy and pyo-salpinx. The last case is too recent to speak of, but not one of the others developed any fever after the operation, owing to my careful attention to the principles of antisepsis. A neglect of antiseptic precautions is criminal in any form of surgery. But this may be carried out with nothing but soap and water. The development of an antiseptic conscience is the chief point.

Dr. Dudley, of Chicago, uses a knot of his own invention, which I like best of all for most of these cases. It is made by entering the needle, with a double ligature, through the broad ligament, carrying it across, and reintroducing, bringing it out on the same side on which it entered. The needle is removed and the loop carried over the whole mass to be tied off and laid between the free ends of the ligature. This is grasped in the thumb and fingers and drawn up tight, then one end is handed to an assistant while the other is pulled tight; and next the other end treated in the same way, and in the same manner it is tied.

MEDICAL SCIENCE.

BY GEORGE J. ZIEGLER, M.D.,
PHILADELPHIA.

If physicians generally would have the following or something similar published in the secular press everywhere, they would greatly help to educate the people and diminish quackery of all kinds.

There appears to be great misapprehension respecting the character and the scope of medical science. It does not consist of a single *pathy* or *ism*, or of many shreds of *pathies* and *isms*, but of all truth pertaining to health and disease in their most extended relations. Hence, *pathies* and *isms* do not represent, and have no place therein, while the real knowledge and truth included in every *pathy* or *ism* belong to the general science of medicine, which is thus of universal compass. The application of the term Allopathy to legitimate medicine is a misnomer, and savors of quackery; while that of Allopathist, applied to the the regular physician, is justly repudiated as expressive of a reproach. The only term ending in *pathy* at all applicable to the science of medicine is *Anti*-pathy, or antagonism to all disease; but even this is too limited and misleading as to its nature and extent, as it only includes the mere prevention and treatment of disease, and omits all the collateral branches of biological and many of surgical science. This law of antagonism and principle of counteraction applies to curative medicine, as it is uniform and universal, and does not admit of any exceptions, much less of such as are implied in the sophistical dogma "*similia similibus curantur*," or like cures like, of homœopathy. The dictum that to cure one disease it is necessary to produce another of the same kind or similar to the one existing, and then that this like, stronger, and conquering disease gets well of itself, is a sheer assumption. The victim of one disease does not want, and should not be afflicted with another disease of any kind whatever, whether the the same (isopathic), similar (homœopathic), or dissimilar (allopathic), but wants to get well in the most direct way as easily and as speedily as possible. This it is the object of scientific physicians to accomplish by the most appropriate physical, mental, and moral means which can be brought to bear upon the case by this law of antagonism with counteracting and antipathic agencies, of which mere drugs of themselves are often of minor importance, though generally useful and frequently indispensable. The basis of medication is generally alimentation. This is often of itself sufficient to cure as well as prevent disease. The regulation of the diet, with the other hygienic measures of pure air, light, heat, clothing, rest, exercise, mental and moral conditions, etc., according to circumstances, being also necessarily in union with this system of counteraction or antipathy, or prevention of disease, this law of antagonism prevails, and *anti*-pathists adopt such measures as are counteractive to the disease, and as tend to restore the equilibrium of health. Drugs are administered in every form, proportion, variety, and way, crude or refined, single or multiple, separate or combined, in small or large doses, and all are

employed as necessary to the case under treatment. Scientific physicians discard all exclusive dogmas, *pathies* and *isms*, as being too narrow and sometimes fallacious; but they counteract disease by the sound, common-sense law of antagonism or anti-pathy. This may not always save life, just as carbonic acid and water may not always save property from fire, yet they are specific therefore, nevertheless. The science of medicine is one and universal in its range and application, and at the same time it is progressive —new discoveries, new truths, new remedies, being constantly added in its onward course towards perfection.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, December 8, 1887.

Thomas M. Drysdale, M.D., in the chair.

Dr. W. Goodell read a paper on

Intra-Ligamentary Cyst.

In it he stated that the three abdominal cysts most commonly met with are the true ovarian, the common parovarian and the intra-ligamentary cysts.

The ovarian is typically multilocular, has a pedicle, and starts from the stroma of the ovary, when the ovary is found. It always grows into the peritoneal cavity, and is probably due to a follicular degeneration of the ovisacs, which explains its multilocular feature.

The common variety of so-called parovarian cyst is typically unilocular, usually unadherent and thin walled. It does not bear inside papillary growths, but it contains a clear limpid fluid. It is wholly extra-ovarian, the corresponding ovary being found either pendant apart from it, or else plastered upon its walls, but yet wholly distinct. The lining membrane of this cyst being identical with that of the tubes of the parovarium, its origin is referred by pathologists to this fœtal relic. To account for its single chamber, it is supposed to originate from some detached loop of the tubes, or especially from a little cyst always found at the outer end of the horizontal tube of the parovarium.

The third variety of cyst is called the intra-ligamentary, senile, or encapsulated cyst. From its site between the folds of the broad ligament, from its papillary ingrowths and its quasi-malignant nature, and also from the difficulties attending its extirpation, it deserves special description, and needs a special treatment.

There are two kinds of cysts encapsulated by broad ligament. The one is a unilocular papillomatous cyst; the other a multilocular papillomatous cyst. Both contain clear fluid. The former is probably a cystic degeneration of one of the imbedded vertical tubes of the parovarium, which represents the rudimentary sexual remnants of the Wolffian body. It is usually more encapsulated by the broad ligament than the multilocular variety, but the connective tissue is looser and less vascular.

The multilocular intra-ligamentary cyst has but a few daughter-cysts, each cyst distended by a clear, limpid fluid and containing exuberant firm papillomatous growths. Its proneness to ingraft itself upon migratory organs and its firm and vascular union to its capsule of broad ligament make its removal far more difficult than that of the unilocular variety. Its origin is questionable, although the presence of papillary ingrowths would point to fœtal tubular relics as the source. Some attribute it to cystic degeneration of supplemental ovarian tissue often found imbedded in the broad ligament at a distance from the ovary. Others refer it to the tubular relics in the par-oöphoron. Lastly, Doron attributes it to stray fœtal relics in the hilum of the ovary. As this theory met every characteristic of this tumor, viz., the papillary ingrowth, its multilocular character and its investment of broad ligament, Dr. Goodell was inclined to accept it. The tumor did not develop in the peritoneal cavity, but growing inwards and into the broad ligament, it parted asunder the two peritoneal folds of the latter. As it burrowed upward it stripped off the peritoneal coat of the womb and bladder, fusing itself with these now naked organs by continuity of structure, and not by mere contiguity. Hence, in the operation for its removal, the womb was liable to be badly wounded and the bladder torn open. Burrowing downwards, it uncovered and soldered itself to the ureters, the great pelvic vessels and the rectum, making its separation here very dangerous and sometimes impossible. Mounting upward from this region, the sac goes in between the two folds of the mesentery, meso-colon and meso-cæcum, and, prying them apart, ingrafts itself upon these viscera. In these cases, a portion of the cyst must be left behind, as the union is too integral to be severed. Another characteristic is the proneness of the

cyst wall to burst and to infect the whole peritoneal cavity with papillomatous poison. Whether this is always malignant is doubtful, for he had seen patients wholly recover whose entire peritoneal cavity was studded with papillary growths. On the other hand, he had had them die in a few months after the operation.

The signs of an intra-ligamentary cyst are immobility and low descent of the sac, vertical elongation of the womb and bladder, embarassment in micturition and in defecation, pelvic pains, unsymmetrical abdominal development, and resonance on percussion from bowels carried up in front.

The operation for the removal of an intra-ligamentary cyst demands great experience on the part of the physician, and taxes all his pluck. These are the cases which are liable to die either on the table or a few hours afterwards from shock. Formerly, when a cyst was found to be intra-ligamentary, the incision was closed and the case abandoned. Now, thanks to Miner, of Buffalo, the surgeon need rarely be foiled.

Since the bladder is often dragged upward and then lies directly under the line of the incision, great care must be taken not to wound it. The cyst should then be emptied, but it must not be lessened in size by the introduction of the hand and the breaking up of daughter-cysts, because the flow of blood would be too great, and papillomatous material might escape into the abdominal cavity. For the latter reason the opening made by the trocar should be securely closed. The collapsed sac is now drawn out of the abdomen and the capsule is divided, little by little, in a circle on a level with the edge of the abdominal incision. The sac wall is then enucleated so as to leave an uninjured cup-like cavity. To do this with the least amount of hemorrhage, the incision should begin at the lateral border of the sac where the spermatic vessels lie. After these are secured, the incision is extended to the site of the womb, where will be found the uterine arteries, which will also be cut and secured either by ligature or by pressure forceps. As the surgeon advances he will have to tie or clamp many blood vessels. The attachment to the womb is left for the last, and it can then usually be brought outside of the abdomen, when it may be often converted into a sort of pedunculated attachment which can be ligated *en masse*. Often the whole sac is shelled out of its capsular nest, without any approach to a pedicle. In the deep portion of the enucleation great care must be taken not to injure the ureters, rectum or the large pelvic vessels. When firm adhesions to important viscera are met with, the adherent portion of the sac must be cut off and left behind, but its secreting layer should be peeled off.

The vast cavity of the empty capsule is treated in one of the following ways, each aiming to exclude it from the peritoneal cavity: (*a*) The edges of the capsular cup are attached to the border of the abdominal incision and a drainage tube is put in. (*b*) Through the flow of the intra-ligamentary wound a catch-forceps is thrust through into the vagina. There it is made to seize a winged rubber drainage-tube, which is drawn up into the capsular cavity. The edges of the capsule are now trimmed and sewn with gut, the one to the other so as to exclude its cavity from that of the peritoneum.

Whenever neither of these modes can be adopted, one large drainage-tube or even two of them should be introduced into the pelvic cavity.

Dr. Drysdale remarked that the paper of Dr. Goodell covered the ground so thoroughly that he could add but little to what had been said. One important point is the extreme thinness of the cyst wall, often met with in these cases, which in his experience had made it almost impossible to get the cyst away without tearing. Another difficulty, peculiar to this form of tumor, was the risk of wounding the great blood vessels of the pelvis when the cyst had burrowed under or became incorporated with them.

Dr. Drysdale understood Dr. Goodell to say that he believed that all operators in removing these tumors had met with the accident of opening the bladder. He was glad to say that in an experience of twenty-six years, he had never been so unfortunate as to open that organ.

Dr. Drysdale believed that true papillomata always proves fatal. The faith of some writers, in the occasional curability of these growths, is founded upon the error of mistaking a benign growth, which resembles them, for true malignant papillomata. These innocent masses of papillary granulations, in fact, so closely resemble the malignant that the microscope alone can distinguish one from the other.

Dr. J. Price has not had experience in the removal of this form of abdominal growth. He is pleased with the free use Dr. Goodell makes of drainage tubes; he himself has used three at one time in complicated operations. He is wishing for some form of perfected continuous irrigation applicable to the after-treatment of abdominal section. He has had

his greatest experience in removal of pustubes, and has met with a mixed ovarian and parovarian growth in many of his patients. Mr. Tait had described two varieties of papillomatous cysts, one having virulent characters and the other benign.

Dr. Goodell, in closing the discussion, said that his experience tallies with that of Dr. Kelly, that some of his patients were eventually poisoned by the virulent character of the cyst-contents, and died a few months later; while the majority were not affected at all. One explanation of these varying results may be expressed in the statement of Virchow that a papillary growth may be benign at an early stage of its development, and may afterwards take on malignancy. The walls of these parovarian, intraligamentary cysts are very thin, as mentioned by Dr. Drysdale. He had called attention in his paper to the danger of wounding the great vessels, and mentioned a case in his own practice, which Dr. Drysdale overlooked. He likes Monsel's solution as an application to oozing surfaces. He has used it freely, in full strength, over the whole capsular cavity, by means of a sponge saturated and squeezed out; or he wets the end of his finger with it and applies it to bleeding points. Our President has been very fortunate not to have wounded the bladder in such operations, for all the eminent operators have reported cases.

Dr. Goodell, speaking on

Resuscitation of Asphyxiated New-born Children,

said that he thought the danger in many of the methods advocated lay in their roughness; they were liable to put out the flickering flame of life. He had seen buttock-slapping and various other violent methods resorted to, to quicken slow breathing, and he was sure that they had extinguished the feeble life of the child. When the child gasps he sometimes blows on the chest, or gently rubs its back, to induce more frequent respiration, and then lets it alone, merely wrapping it up warmly. But if there should be no effort at respiration, and the heart still beats, then any of these rougher methods are permissible. In the Preston Retreat he was accustomed to lay the child across his hand, the head and arms hanging down on one side and the limbs on the other side of the hand; then he gave it a quick upward movement, and, as it came down, he doubled the child up, with its knees to its chin. This folding and unfolding of the child favored the entrance and exit of air. But after it had gasped once he stopped all violent movements and practically let it alone. In one case, where he had been called in, in consultation, one of tedious labor, the child of a physician, after all efforts had been made to induce respiration, they were discontinued as fruitless, and the child was laid aside as dead. In a few minutes afterwards it was heard to cry, and is now living. In another case, after every method of inducing respiration had failed, the child was pronounced dead by the father, a physician, and also by the attending physician. To keep the body sweet it was placed outside of the window on the roof, the night being a cold one. When the child was taken in to be washed before it was laid out, it was found living, and it is now alive. On one occasion, at the Preston Retreat, a child was laid aside in a corner as dead, after he (Dr. Goodell) had used various methods of artificial respiration. An hour later the nurse took it into the bath-room to wash its body, and she found it breathing. It, also, lived.

Dr. Longaker wished to emphasize the principle of not doing too much to quicken respiration. He feels sure that one child would have had a better chance for its life if he had not inserted a catheter into its trachea. He succeeded in making the child breathe, but the air vesicles were injured by over-distension, and death resulted twenty-four hours later. Rubbing the back is a very good method. Dr. Champneys, in the *Amer. Journ. Med. Science*, April, 1886, recommends holding the child with its head in a dependent position, to relieve anemia of the medulla, which he thought the cause of asphyxia in many cases.

BALTIMORE ACADEMY OF MEDICINE.

Regular Meeting, Dec. 20, 1887.

A Case of Aneurism of the Terminal Branches of the Auricular Artery.

Dr. Hiram Woods presented a case of a colored boy, 17 years old, with an aneurism of the terminal branches of the auricular artery. When he was 7 years old his mother noticed a little lump on the front of the ear and another small lump about as big as a pea on his neck. These lumps gave no pain and did not seem to grow for a long time. About three years ago they began to get larger and gave pain. The mother pricked the one on the ear with a pin, when it bled and became empty, but filled up again soon. She repeated this operation several times with the same result. The lump on the neck was

scraped open and bled for a long time. When Dr. Woods examined the patient he found that the tumor on the ear pulsated, collapsed on pressure and filled up again when pressure was removed. Pressure on the carotid artery stopped it. It was seen that three or four branches supplied this aneurism, and when compression was exercised on both the anterior and posterior auricular arteries, pulsation in the aneurism ceased entirely; but when only one of the above-named branches was compressed the pulsation was lessened but not entirely stopped. In looking into the literature of the subject he found that Buck had never seen a case himself, but recorded several others. One was a cirsoid aneurism in which the persulphate of iron had been used. In another case the tumor was large and the hemorrhage profuse. Ligation of the external carotid was performed. A third case reported by Kipp, of Newark, was attributed to a blow. It was the only case he could find which had followed an injury. Roosa mentions a case of Gruenings which was almost a duplicate of the case presented by Dr. Woods. In this case a subcutaneous ligature of the arteries was done. Politzer and others have reported cases which were treated in various ways:

1. By passing through the tumor threads saturated with iron. He considered injections of iron dangerous. 2. Ligation of the arteries and scraping the sac. 3. By using thermo-puncture. In his case he had passed a needle armed with a thread under the arterial branches, and found that the pulsation had almost disappeared, although the threads had not been tied. The subsequent treatment was to ligate the vessel and scrape out the sac.

Dr. J. J. Chisolm thought it was very curious to see that the pressure of the thread had almost arrested pulsation before it was tied.

A Case of Intussusception.

The President, Dr. W. C. Van Bibber, then presented an interesting specimen of intussusception of the ileum with the following history. The patient, a woman, who lived in the country, was taken with pains in the right iliac region, and at times these pains were violent. She was for five days under a local physician who gave purgatives, enemas and anodynes with only temporary relief. On the sixth day after a hot rough ride from the country, she came under Dr. Van Bibber's care. He found her in violent pain, and felt a large hard tumor in the right iliac region. There was also sensitiveness over the whole abdomen. She said there was no hemorrhage from the bowels and no evacuation from the bowels for several days. He had twelve leeches applied and gave purgatives, and later found that the tumor had almost disappeared. He thought this was singular and made an examination by the rectum and vagina, and found the tumor deeper down. She had pains after this and soon vomiting, which was, however, not stercoraceous. She grew alternately better and worse, and finally sank into a collapse and died. The autopsy, thirty-six hours after death, showed nothing abnormal in the abdominal cavity, except in the portion involving the parts contiguous to the ileo-cæcal valve. There was also a slight general peritonitis, most intense near the point of lesion. The condition of intussusception had been recognized some time before death, but after consultation with Dr. L. McLane Tiffany and Dr. Claude Van Bibber he considered an operation not advisable.

Dr. Wm. H. Welch, at the request of Dr. Van Bibber, demonstrated the specimen. He said that the most common situation for intussusception in the adult is the lower part of the ileum. In this case the intussusception, which is descending, extends to within five inches of the ileo-cæcal valve, the whole part intussuscepted being ten inches in length. The specimen shows well the anatomical relations of intestinal insusception, viz.: the entering or internal layer, the returning or middle layer (the two constituting the intussusceptum), and the receiving or external layer or sheath, this being the intussuscipiens. In consequence of the disturbance of circulation due to the displacement of the mesentery there are œdema and hermorrhagic infiltration of the intussuscepted intestine, particularly of the lower seven inches. The entering intestine is much contracted and filled with blood; between the entering and the returning layers (serous surfaces in contact) there is a mass of clotted blood, and between the returning and the receiving layers (mucous surfaces in contact) there is bloody mucous. The intestinal walls are hemorrhagic, in fact the condition is that of a genuine hemorrhagic infarction of the lower two-thirds of the intussusception.

The most interesting feature of the case is its causation. In the entering layer, about three inches from the top of the intussusception, is a polypus, somewhat larger than a pigeon's egg, which, on microscopical examination, is found to be composed of dense fibrous tissue infiltrated with blood. It is attached by a broad pedicle. The curious thing is that the polypus is not situated at

the lower extremity of the intussusception.

According to Leichtenstern's statistics, which are the most complete we possess, a polypus has been found in thirty out of about six hundred cases of intussusception. Brinton reached the same result by the analysis of his statistics (a polypus in five per cent. of the cases). Medical literature is full of reports of intussusception depending upon polypus. It can hardly be doubted, therefore, that a connection exists between polypus and the production of intussusception; and it has generally been considered that the mechanism by which the intussusception is produced is more readily understood in the cases with polypus than in other cases. The accepted and apparently correct explanation is that the polypus by its weight draws down the part of the intestine to which it is attached and invaginates it. One would naturally expect, in such a case, the polypus to be at the lower extremity of the intussusception; but, in the present case, the polypus is found, not at the lower end, but near the top of the entering layer of intestine. How is this to be explained? If we regard the polypus as in any way concerned in the production of the intussusception,—and one would certainly be unwilling to reject a causative factor so manifest,—an explanation of the manner in which the intussusception was produced in the present case may be deduced from the interesting results obtained by Nothnagel in his experimental work on intussusception. Nothnagel aims first to test the two prevalent theories concerning the causation of intussusception: one theory being, that the intussusception is due to a spasmodic contraction of a part of the intestine, the contracted part becoming invaginated into the adjacent intestine, either above or below; the other theory being that intussusception is referable to paralysis of part of the intestine. Nothnagel's experiments were made upon rabbits placed in a bath of warmed physiological salt solution, the intestines being allowed to float out into this solution, in which it has been shown that the conditions of normal peristalsis are not much disturbed. Nothnagel was unable to obtain any experimental support for the paralytic theory of intussusception, but he was able to produce intussusception by causing spasmodic contraction of a part of the intestine. By applying the electrodes of a Faradic battery to the intestinal wall he was able to cause a firm circular contraction of the intestine at the seat of application. If the electric current was strong, this contraction extended a considerable distance upward, but only a short distance downward. In a large number of cases Nothnagel observed that a descending intussusception was produced, beginning just below the point of application of the electrodes. Within one or two minutes as much as four inches of intestine might become invaginated. The intussusception grew in length, however, not at the expense of the intestine above the entering layer, but at the expense of the receiving layer. By marking a point on the entering layer at the neck of the intussusception, Nothnagel found that this did not descend or change its relations. On the other hand, by marking a point on the receiving layer he observed that this was gradually drawn upward, apparently by a contraction of the longitudinal muscular coat, and after passing over the bend joining the returning and receiving layers this point descended into the returning layer. In this way the intussusception grew by the receiving layer being gradually drawn over into the returning layer, and the latter in turn being transformed into the entering layer. This explanation of the possible production of intestinal intussusception is contrary to the generally accepted views, but it is supported by the relations of the polypus present in Dr. Van Bibber's case; in fact this case may be regarded as a most important contribution to our knowledge of the manner in which intussusception may be produced.

It is apparent from the examination of this specimen that if laparotomy had been performed, and the intestine in its present condition had been replaced, that it would certainly have undergone necrosis. The only practicable operation when the intestine is the seat of an intense hemorrhagic infarction, as in the present instance, would be the resection of the entire intussuscepted intestine.

In opening the discussion, Dr. James Carey Thomas, on observing the thickness of the intestinal walls, in the specimen exhibited, asked if this hypertrophy was not very great for the short time.

Dr. Wm. H. Welch thought that the history of this case showed that this condition of intussusception had been going on for some time.

Dr. Christopher Johnson mentioned a case of his own, of a woman with violent pains and frequent vomiting, and from whom thirty inches of the small intestine were passed by the bowel, and the patient recovered.

Dr. Wm. H. Welch said such cases had been observed. Peaslee reported a patient who passed five feet of intestine, and Cruveil-

hier reported a smiliar case in which over nine feet of intestine had been passed.

Dr. A. K. Bond thought that the manner of invagination and the relation of the different layers could be partially explained by the difference of friction between the serous and mucous surfaces.

Dr. Wm. H. Welch thought that the matter of friction could be entirely left out, as the difference was scarcely appreciable in the causation of intussusception. He said that it was very common to find a condition of intussusception at the autopsy when there had been no suspicion of it in life, but the absence of inflammation showed that the invagination had occurred at the time of death, probably during the death agony.

Dr. W. C. Van Bibber, in closing the discussion, spoke of the repeated attacks of colic in his case and of the diagnosis of intussusception before death. He also spoke of Dr. Warren's (of Boston) experiments of taking out part of the intestine of a dog and allowing the animal to recover.

Dr. James Carey Thomas then reported a case of

Pneumonia Presenting Unusual Symptoms.

A man, aged 47, was worried and anxious on account of his business and had been complaining for some time. He fainted once in a Russian bath and struck his shoulder, bruising it. He went on ailing and feeling badly. His wife noticed that he had fever, and the week following he showed symptoms of typhoid fever. He had no diarrhœa, no pain over his lungs, no expectoration and little or no cough. All his uneasiness was situated at the pit of the stomach. He had had typhoid fever ten years before and this was probably not a second attack, although his previous attack had commenced in the same way. On the second or third day some crepitation was discovered in the right lung and the whole lung became solid. Eight days after, there was defervescence and the patient was very faint. The temperature was normal. Three days later a pneumonic trouble was found in the left lung. Later he did well, had no fever, pulse was normal and respiration 20, and he had a good appetite. On Sunday he took a cold bath, which brought on a pleurisy. The interesting points about the case were consolidation with crepitation and absence of pain, cough and expectoration. In reply to Dr. William B. Canfield he said that in both lungs the normal vesicular murmur could be now heard.

Hospital Notes.

Pennsylvania Hospital.

(Service of Dr. James H. Hutchinson.)

Pleurisy with Effusion; Differential Diagnosis; Indications for Tapping.

At his clinic at the Pennsylvania Hospital, Wednesday, Jan. 4, Dr. Hutchinson reviewed the history of a case of acute right-sided pleurisy with large serous effusion, occurring in a lad nine years old. The attack had followed exposure, and its onset was violent —the chill being severe and prolonged, and the temperature reaching 104.5°. The subsequent effusion was of such quantity that only a limited portion of the apex of the lung remained in contact with the chest walls. In speaking of the differential diagnosis of this disease from pneumonia, the following points were emphasized as being of special value: the shifting of the line of dulness occurring in pleuritic effusions with each change of the patient's posture; the absence in this disease of vocal fremitus and resonance, while, in pneumonia, they are increased; the marked alteration in the latter disease of the normal pulse-respiration ratio; and, finally, the dislocation of the neighboring organs produced by large effusions, pneumonia not being marked by such changes. Concerning the treatment of cases such as this, antiphlogistic measures were regarded as of value during the stage of invasion—cupping the affected side, exhibition of antimonials, etc. Reference was also made to the "dry" treatment, which might be adopted at a little later period of the disease, when the effusion of serum is about commencing. This is a favorite plan of treatment of Dr. Osler, of the University of Pennsylvania, and consists in the restriction of the quantity of fluid received by the patient to the smallest possible proportion, and in the administration, at the same time, of saline cathartics, with a view of carrying off by the intestinal tract a large quantity of fluid that would otherwise be effused into the pleural sac. Dr. Hutchinson cautioned his hearers against pushing this plan of treatment to the extent of seriously weakening their patients.

In cases where, in spite of restraining measures, large pleural effusions have occurred, the lecturer deprecated the adoption of tapping as a routine method of getting rid of them. He said that in his experience the operation was followed in the majority of cases by a return of the fluid, and that,

whereas it may have been serous before the tapping, it was apt to become purulent after it. He, therefore, considered the measure as justifiable only under the following conditions: First, when the effusion is so rapid and large, and respiration is so seriously embarrassed in consequence, that any delay in affording relief would endanger the life of the patient; second, when the effusion has become purulent in character, or, in other words, has become an empyema; third, when, after a reasonable period spent in endeavoring to procure absorption by the administration of appropriate remedies, the effusion shows no disposition to disappear.

Should it be determined to resort to this operation, the effusion being *serous*, Dr. Hutchinson advocates the use of the aspirator. When, however, an *empyema* exists, he recommends the making of a free incision and the insertion of a fenestrated tube of sufficient calibre to insure free and complete drainage. In support of this view, he cites a case, now in the hospital, which was rapidly convalescing with most satisfactory results from an operation of this kind.

Emphysema with Mitral Insufficiency.

The patient was a woman, aged fifty-eight. She was brought to the house several days before gasping for breath, deeply cyanosed, and with a frequent hacking cough. There was a history of exposure to wet and cold, soon followed by cough and dyspnœa. Physical examination revealed an emphysematous condition of the lungs, bronchial tubes choked with mucus, and a mitral regurgitant murmur at apex of heart. This latter lesion was a result of the long standing obstruction to the free flow of blood through the lungs. The cyanosis was produced by the sudden excess and accumulation of secretion in the bronchial tubes and the consequent inadequate oxygenation of the blood. Carbonate of ammonia had been given in five grain doses every two hours in combination with digitalis, and this treatment had effected a marked amelioration of the woman's more distressing symptoms. In closing, the lecturer said that he regarded digitalis as far superior to any of the drugs that had been recently introduced as substitutes for it. He did not consider strophanthus, adonidine, or convallaria, as at all comparable to it, either in power or rapidity of action.

—A supposed case of leprosy, at Atlanta, has been reported to the Illinois Board of Health. A physician has been sent to Atlanta to investigate.

Periscope.

Ustilago Maydis as an Oxytocic.

Dr. W. A. N. Dorland, of the Philadelphia Hospital, after a study of ustilago maydis, summarizes his results as follows in the *Medical News*, Nov. 5, 1887:

1. *The toxicology and physiological action of the drug.*—No cases of poisoning in man by the drug are on record. That it is, however, possessed of toxic properties in large doses has been proved by Mitchell. He found that in the lower animals, in large doses, it acted violently upon the spinal cord, paralyzing first the sensory, later the motor tracts; finally involving the motor, and probably also the sensory nerves. Like ergot, then, it is probable that the chief force of the drug, in toxic doses, is expended upon the nerve centres, producing a toxic paralysis.

The action of ustilago upon the uterus has been more carefully noted. After the ingestion of a sufficient amount, in from twenty minutes to half an hour, the pains, if present, are increased in severity, in frequency, and in duration, presenting a marked *clonic* character, following each other in frequent succession, with a decided intermission between each. In this respect it differs decidedly from the action of ergot, which, in full doses, produces one continuous, *tonic* spasm of the uterine muscle. It is this property of ergot which has, when administered before the delivery of the placenta, produced in so many instances the irregular contractions of the uterus, of which the hour-glass is a well known example. The employment of ustilago seems to be entirely free from such unpleasant complications. In addition to being a valuable adjuvant to stimulating weak uterine contractions, ustilago seems to possess the property which some years ago was ascribed to quinine: namely, that of exciting uterine pains when these were entirely suspended.

As to the time required for the action of the drug to become apparent, it may be said that it differs in different cases, depending undoubtedly upon the rapidity with which it is absorbed from the gastro-intestinal tract and carried into the system. In only two instances did it require over thirty-five minutes before the ustilago acted upon the uterine tissues, and in one case most of the drug was ejected by emesis. In the remaining seven cases the average time required was twenty-five minutes.

The effect produced by ustilago upon the other unstriped muscular tissues of the

body has not been inquired into. Probably it produces the same increase of intestinal peristalsis, and the same rise in the arterial pressure due to vaso-motor spasm, as is produced by ergot. This is yet open to investigation.

2. *The indications for the employment of the drug.*—The author considers the first indication for its use to be the failure of the pains, with *complete dilatation of the os uteri.* In none of the cases was the drug employed until the pains of labor had either become so weak that they were inefficient to accomplish the expulsion of the fœtus, or until they were entirely suspended. The second indication for its use is the *inefficiency or entire suspension of the parturient pain.* After the ustilago had been taken, it may also be noted that in no case was there the slightest tendency toward a post-partum hemorrhage. In each case, after the expulsion of the placenta, the uterus remained in a state of firm contraction. While during the three months the great majority of the remaining cases, in which the customary ergot had been employed, showed no tendenry whatever toward this alarming accident, in two instances, however, was there such an occurrence demanding prompt attention. The third indication, then, for the employment of ustilago is *a condition of uterine inertia threatening or producing post-partum hemorrhage.*

3. *The dose and mode of administration.*—The preparation of ustilago employed in all reported cases, as well as in his own, was a good fluid extract. The dose of this varies from one-half to two drachms, one drachm being a fair average. This may be repeated at intervals as required. If necessary, it may be used hypodermically in doses of from five to fifteen minims.

The author states that the advantages of ustilago over ergot are (1) that it does not produce irregular contractions, with all the consequent complications and sequelæ; (2) containing but 2½ per cent. of fixed oil, while ergot contains from 25 per cent. to 28 per cent., the dangers of absorption are reduced to a minimum; and, finally, (3) as it can be procured at a cost of 50 per cent. less than that of ergot, it seems to be in a fair way toward supplanting the latter in obstetrical practice, should the results of the investigations thus far be confirmed hy subsequent researches.

—The Marine Hospital Bureau is informed that cholera prevails in Santiago and Valparaiso, and that Peru has established a quarantine against nearly all the Chilian ports.

Suction in the Removal of Foreign Bodies from the Bladder.

Reginald Harrison, F.R.C.S., says in the *Lancet*, October 29, 1887, that the chief difficulty connected with the use of the lithotrite for elongated bodies is the fact that the foreign body is invariably seized at right angles with its long axis. He has, therefore, discarded the lithotrite as an extractor, and trusted to a large-eyed evacuating catheter, such as he uses for lithotrity, and a rubber wash-bottle connected with it, by means of which he can fill and empty the bladder with a stream of water of considerable force. When it is remembered that most foreign bodies introduced into the bladder are of an elongated nature before they become nuclei for stony concretions, this method of removing them at once commends itself. If a rubber bottle is attached and a stream of water is forced into and out of the bladder, it will be found, as a rule, that the end of the foreign body is sucked into the catheter, and in this way may be withdrawn.

One of his recent cases, he says, was a curious one, and was seen in consultation. A middle-aged healthy man a month before the consultion passed a piece of bacon rind about two inches in length up his urethra; this disappeared. He introduced a week afterwards, up the same canal, a stiff pigs's bristle about five inches in length, which also disappeared. Ten days before Mr. Harrison saw him he felt a severe pricking sensation, and at once confessed his indiscretions to his medical adviser. Dr. Harrison passed a soft instrument down his urethra, and distinctly felt something in the prostatic urethra. He then passed a large-eyed evacuating catheter into the bladder, and attached a powerful rubber syringe to it, such as he uses for the removal of stone fragments after lithotrity. After a few movements of the syringe he felt that he had engaged something in the eye of the catheter, and on withdrawing the latter, the bristle, beautifully coated with phosphates, came with it. Of the bacon rind he neither felt nor heard anything more. These manœuvres were quite easily carried out on the author's consulting-room sofa without an anæsthetic. Some weeks previously he had removed a piece of gum-elastic bougie (No. 6), three inches in length, in the same way. To commence with, he felt, as the water current was being injected, the bougie strike against the eye of the catheter with its long axis, and was therefore not caught. He then distended the bladder with another syringful of water (four ounces), when at once the end of the bougie became impacted in the eye of

the evacuating catheter, and was withdrawn like the bristle. The additional amount of water permitted the bougie to rotate in the bladder. Still more recently, by the same process, he dislodged a renal calculus which he believes was impacted in the orifice of one of the ureters, where for some weeks it had caused much irritation.

Baths in Childhood.

Calatraveno, in a paper on this subject in *El Progress Ginecologico*, July 10, 1887, says: The great importance of bathing establishments in the treatment of disease in adults has long been recognized, but the principle has not been applied to any great extent in the treatment of disease in children. In view of the great number of children who are affected with chronic diseases, especially scrofula and tuberculosis, and the eminent advantages which are to be obtained by the systematic use of water, the author makes a plea for its more extended use. Children with these diseases should be removed to a station by the sea-shore, where the constant inhalation of the pure atmosphere will serve as a powerful tonic. The beneficial effect of playing in the warm sand must not be overlooked. If the child is feeble and the water cool it should not be used more than five minutes at a time, whether by pouring, sponging or immersion. Small quantities of sea-water may also be drunk with advantage with each bath. Of course the child should not be bathed while the body is warm, nor within three hours after the last meal. Currents of air should be avoided during and after the bath, and the child should be encouraged to take some exercise immediately after being dressed. Of the medicinal waters which are of service in the treatment of scrofula, the sulphur waters of all kinds are effective, but those containing sodium-chloride are more so. For the poor who cannot go either to a mineral spring or to the sea-shore, hygienic treatment at home is quite possible, artificial salt or sulphurous water being readily and cheaply obtained, and home treatment by rubbing and douching being also possible. For children from one to three years of age the temperature of the bath should be 60° F. to 68° F., and the back, arms and legs should be briskly rubbed every day. From six to ten years of age the rubbing should be general, and the duration and frequency of the baths or douches regulated by the resisting power of the patient. If sulphur baths are indicated, a few grains of sulphate of potash added to the water of the bath will procure the desired condition. If such means of treatment were more generally adopted with scrofulous children there would be fewer developments of phthisis among them, and a more robust condition of health in general.—*Archives of Pediatrics*, December, 1887.

The Use of Fats and Fatty Acids in Chronic Wasting Diseases.

Senator has a paper on this subject in the *Centralblatt für Kinderheilkunde*, Sept. 3, 1887, which is abstracted in the *Archives of Pediatrics*, December, 1887.

In chronic diseases, accompanied with great emaciation, the custom is to prevent loss of fat as much as possible, and also to administer fats, if they can be borne. The fat in ordinary nutriment will fulfil both these indications, while it acts also as a reserve supply, and tends to limit the albumen metamorphosis, and diminishes the disintegration of the albumen in the nutriment as well as in the body itself. Fluid fats, however, easily become intolerable, and especially is this the case with cod-liver oil. The author, therefore, has made use of the more solid fats in the treatment of these diseases, especially taking spermaceti, which was long ago used in the treatment of disease in children, and powdering it, administering it in teaspoonful doses, either alone or with the addition of three parts of sugar. After the use of fifteen to twenty grains of the spermaceti daily for some time no considerable quantity of fatty acids could be recovered from the fæces. A mixture of spermaceti and oil was also used in some experiments upon dogs, and only a portion of it could be recovered from the fæces; the remainder must have been digested and absorbed. Since fats are broken up in the intestine into fatty acids and glycerin, and the latter may undergo acid fermentation (which may partly account for the disturbances of digestion occurring after the use of fats), and since the fatty acids will have the same effect upon the tissues as fats themselves, it occurred to the author to have coated pills made, containing each four and a half grains of palmitin acid and two grains of oil acid, and these were well borne by the stomach. The author deemed it feasible to administer fats with alkalies,—that is, in the form of soap,—believing that the same effect upon the tissues would be produced as by the use of the fats alone. A portion of the fats ingested must be converted into soap in the intestine, and this labor might be saved by administering the soap *per se*. Coated pills were made for the author from medicinal soap dissolved in

gum. It was also given in the form of powder, with the addition of sugar or oil sugar, and could readily be taken in this form. Good results from this treatment were seen in diabetes, phthisis, chronic icterus, and cirrhosis of the liver, and no accidents occurred. It is desirable that, in addition to the soap, spermaceti and cod-liver oil should be given whenever possible.

A Sign of Live Birth in Certain Cases of Suspected Child Murder.

Dr. F. W. Higgins, in a communication to the *Med. Record*, Dec. 17, 1887, comments upon the well-known fact that one of the most difficult questions which the medical jurist is called upon to decide is that of live birth where foul play is suspected. The hydrostatic test is about the only one which is at all conclusive. By this test, properly performed, one may quite positively affirm whether respiration has or has not taken place. But while killing the child in utero is criminal, and killing it after birth is murder, there is no punishment if the child be killed before it has been completely born, even after respiration has been fully performed. Nor does there seem to be any test given, by any authority, by which one may determine whether the birth was complete when death was inflicted. With a view of helping to furnish such a test, he reports an examination of an infant, which collateral evidence showed was strangled at birth. The choking caused death, not so much by suffocation as by compression of the jugulars and hemorrhage at the base of the brain, and also by the condition found in the heart. The cord was cut off close to the body. Both cavities of the heart were found filled with dark, *frothy* blood. The conclusion arrived at was that compression had lessened the pulmonary circulation just as it was being established. The heart, still beating and unsupplied with blood, had *sucked* in air through the divided umbilical vein. Evidently, he concludes, this could have happened only after the body had come into the world and the cord, the last bond to the mother, had been severed.

A Case of Bilharzia Hæmatobia.

In the *Glasgow Medical Journal*, December, 1887, Dr. A. Napier reported the case of a man, 28 years old, who had enjoyed good health until he went to Egypt in February, 1882. In that country he seems to have enjoyed fair health for about eight months, when he had an attack of piles and internal fistula, ascribed to sleeping three nights in the desert. This was soon followed by his present ailment, the first indication of which was the discovery of a bright and red blood stain, of the size of a half-crown piece, on his shirt. Then daily, for two months, he lost a little blood, bright-red in color, and varying in amount from thirty to sixty drops with each act of urination, the blood coming at the end of the stream. When this had continued for two months, he was suddenly attacked with pain, dull or sub-acute in character, and radiating from a point in the middle of the lumbar region. With this began the passing of small shreddy clots or sloughs, along with the bright red blood. At the end of another month—that is to say, after three months' illness, urination was one day found to be impossible; distension of the bladder became very distressing, and at last, after many fruitless efforts and much hard pressure, a gelatinous clot came away. This was about an inch in length, one-half an inch in diameter, cylindrical in shape, and transparent or slightly milky, not unlike jelly. Similar but much smaller clots subsequently came away from time to time. His other symptoms, briefly stated, were great irritability of the bladder, and seminal emissions at first with each urination, subsequently only at night, and afterwards ceasing; emaciation; general debility; improvement, and a return to fair health, with general tonic treatment and a suitable change of climate; the persistence of the loss of blood, even if slight in amount, and the evidence of the continued presence of the parasite in the urinary apparatus, probably in the kidneys. The patient states that this form of disease is very prevalent in Egypt, and believe that about fifty per cent. of the inhabitants of Egypt living along the Sweet Water Canal suffer from it. This he ascribes to the foul canal water they have to drink.

Treatment by salicylate of soda was suggested by the patient, as a friend of his own, who was greatly exhausted by the disease, obtained much benefit from salicylic acid after the comparative failure of the usual climatic treatment. This patient is inclined to think that he was benefited to a slight extent by the salicylate of soda.

—At the meeting of the State Board of Health, at Lansing, Michigan, January 11, Professor Vaughan reported a successful experiment of producing in a cat a disease similar to typhoid fever in the human being, by the use of the germs found in the water used by the victims of this disease at Iron Mountain, Michigan.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record. 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE PHYSICIAN AND THE SURGEON.

We have received from one of our correspondents a very interesting communication upon the relative positions of the physician and the surgeon. The writer belongs to the former class, and seems to feel that some slight is put upon physicians by the popular applause awarded to surgeons. There can be no doubt that, as he says, the present age is one in which surgery is glorified. The very character of its operations is such as to attract public attention; and the boldness and safety with which organs, long deemed beyond the reach of surgical skill, are now cut into or cut out, excites a natural wonder at, and admiration of, the courage and success of those who practice surgery. It is true also that the work of the physician is usually less conspicuous than that of the surgeon, and that he often employs the highest order of intellect in labors which are performed in comparative obscurity. But we think it is a mistake to suppose that the community does not appreciate physicians as highly as it does surgeons. In our own country there are no names which have been more honored than those of Rush, Chapman, Wood and Flint, who have left us, or of Stillé, Da Costa and Weir Mitchell, who are yet with us.

But fame is not the highest reward for work well done; and, in estimating the opinions of the world upon those who practice the healing art, it must not be forgotten that physicians, as a class, have a much better opportunity than surgeons to secure the regard and affection of their patients. This is a fact which ought to compensate the former for the loss of some of the admiration which the latter secure, because their work and its results are more striking to the senses. The position occupied by thousands of men who practice medicine modestly and quietly, and whose names are never heralded to the world, is in our opinion one of the noblest to which a right-thinking man can aspire. To them the lives of their patients are daily entrusted; their profoundest secrets are confided; in them the deepest confidence is reposed; they often follow from birth to death the career of those who are under their care; and when their office is faithfully performed, no one in the community is more loved and honored than are they.

Surely such a reward leaves no room for envy; and those who enjoy it need never grudge the due meed of praise to those who labor in another part of the same field.

A FRENCHMAN'S VIEW OF MEDICAL EDUCATION IN THE UNITED STATES.

In several numbers of the *Bulletin Médical*, in December, 1887, DR. ARTHUR HUGENSCHMIDT, of Paris, who was recently graduated, first in dentistry and afterward in medicine, from the University of Pennsylvania, publishes an interesting series of papers on medical education in the United States. In these papers there is much which might instruct our own countrymen; for Dr. Hugenschmidt has studied his subject very thoroughly and presents it very clearly and tersely. He describes the regular schools of medicine, and their methods and standards of teaching, in a way which does ample justice to their different merits. He also gives a fair account of the eclectic and

homœopathic schools of the United States; and devotes some space to the women's medical colleges, paying a high tribute to their excellence, and especially to that of the Woman's Medical College of Philadelphia.

One of the best written parts of this series of papers is that in which the author describes the life of the medical student in America. This description includes an account of his habits of life and habits of study. The former he thinks pleasant, though trying to the digestion; the latter he thinks severe upon the mind and the body. Still, he thinks the intense application demanded of medical students in this country makes three years of study here equal to five or six years of study for most French medical students.

It is always interesting to see how the manners and customs of any country impress those who are not brought up to them, and it is usually possible to draw some lessons of profit from a sensible and amiable review of them by a foreigner. So the papers of Dr. Hugenschmidt may, if rightly considered, furnish something more than entertainment to us, on account of the generally complimentary tone in which they are written. Some of the defects in our system of medical education, which he points out, may be more easily remediable than we think, and it will be wise to heed his friendly criticisms.

THE PERIOD OF CONCEPTION.

A very important point to be borne in mind, in making a scientific estimate of the duration of pregnancy, is the fact that conception may occur very soon after a productive intercourse, or when an interval of some days has elapsed, or it may be even after an interval of one or two weeks.

We state this as a fact, because, although we do not feel sure that it cannot be disproved, we do feel sure that it is a reasonable inference from what is frequently observed. It is our conviction that the spermatozoa may maintain life for a comparatively long period in the body of a woman; that they may meet an ovum under circumstances favorable to its fecundation at any time in this long period; and that the determination of the time at which this coincidence may occur is more or less accidental. The menstrual epoch in woman differs materially from the period of heat, or rut, in the lower animals—being unfavorable to conception; and a fruitful coitus is usually one which occurs long enough before the menstrual molimen to lead to impregnation and a successful lodgment of the ovum, before the congestion and flux of this period threatens its vitality or breaks up its nidus.

The period at which impregnation occurs cannot be said to be that of the fruitful coitus; on the contrary, it is probably in most cases later than this by some days or weeks, and all calculation of the duration of pregnancy, based upon a different assumption, are likely to prove misleading.

WASHING OUT THE STOMACH IN CHILDREN.

At the last meeting of the German Congress of Naturalists and Physicians, at Wiesbaden, Dr. Lorey, of Frankfort, gave an account of forty-three cases of children, some as young as two years old, affected with dyspepsia, in which he practiced *lavage*, or washing out the stomach by means of an œsophageal tube. The indications for this operation seem to have been: fulness of the stomach and fetid breath. In the case of thirty of his little patients, Lorey says that from one to three washings with a weak solution of chloride of sodium cured their dyspepsia. He therefore recommends this plan of treatment for general adoption.

Such a recommendation is not likely to be followed in this country, where the introduction of a stomach-tube, for the cure of simple dyspepsia, in little children, would probably be regarded as an unpardonable brutality. If the advocates of this method were aware how much can be accomplished, in cases of overloaded stomach and fetid breath, with small and repeated doses of calomel, or even of naphthalin—not to say castor oil—we do not think he would be so cruel to his little patients as to force them to submit to washing out their stomachs.

PTOMAINES.

The proceedings of the German Medical Society of Philadelphia, which we published in the last number of the REPORTER, relate to a subject of great importance to all physicians. A large part of our knowledge in regard to the development of poisonous products by the decomposition of animal tissue in the intestinal canal is of comparatively recent date, and the significance of the words "ptomaine" and "leucomaine" is not yet thoroughly understood by the profession at large. Some of the details of the study of this subject involve abstruse biological and chemical questions; but, without following them up, it is desirable that some idea of what is now believed by those who have made special investigations in regard to them should be circulated as widely as possible.

The paper of Dr. Wolff was so full of detail that we thought it wise to condense it somewhat. In the discussion which followed it, our readers will find practical applications of the current theories in regard to ptomaines which will interest, and may profit them.

THE TREATMENT OF STERILITY.

The paper of DR. WEINTRAUB on sterility in Syrian women, which is published in this number of the REPORTER, contains, not only an interesting description of the effects of the condition in the East, but also a very useful and practical suggestion in regard to its proper treatment everywhere.

It is not so common in Europe or America for women to lament the fact that they are barren as it is in Oriental lands. The complaint here is usually that they are too prone, or too liable, to conceive. Still it does sometimes happen, even in our own land, that a husband or a wife will appeal to the physician for advice how to overcome the obstacles to conception. In such a case the suggestions of Dr. Weintraub, which bear the mark of sensible thought, and which have been carried out with so much success in her own practice, deserve to be carefully considered by the physician.

PAMPHLET NOTICES.

THE TRUE NATURE AND DEFINITION OF INSANITY. By C. H. HUGHES, M.D. From the *Alienist and Neurologist*, October, 1887. 30 pp.

THE CONFIDENCE OF THE PUBLIC IN NON-PROFESSIONAL PRESCRIPTIONS. By W. S. LEONARD, M.D. Manchester, N. H.: Printed by John B. Clarke, 1887. 17 pp.

IMBIBITION OF POISONS. By PROF. JOHN J. REESE, M.D. From *Medico-Legal Journal*, for September, 1887. 7 pp.

A CASE OF GASTROSTOMY FOR CANCER OF THE ŒSOPHAGUS. By J. COLLINS WARREN, M.D. From the *Medical Record*, November 5, 1887. 8 pp.

—Dr. Hughes's pamphlet is so interesting that we were not altogether surprised to find it printed as an original communication in a medical journal of this city three months after it had been published in the *Alienist and Neurologist*, and about a month after the reprint from this journal was on our table for notice. The author supports the physical, as opposed to the metaphysical view of the nature of insanity, and holds that it is a psycho-somatic disease, and contends that "wherever the *ante-mortem* and *post-mortem* search has been sufficiently thorough, somatic as well as physical aberrations have been found." We are not familiar enough with the literature of alienism to be sure that this statement is absolutely correct. But we would accept it with some reserve.

—Dr. Leonard's paper has been made the foundation of an Editorial in the REPORTER for December 31, and we simply call attention to it here as a very interesting and suggestive presentation of an important phase of medical practice: the duty of the physician to consider the needs of his patients with a due regard to their opinions and just desires.

—Prof. Reese answers in the negative the question: Can chemists decide whether arsenic found in the tissues of a dead body has been administered before or after death in cases in which arsenic has been injected into the body after death, presumably for the purpose of concealing a crime? He describes experiments conducted under his direction, in order to determine this matter, and refers to others, suggesting further experimentation with precautions calculated to prevent certain errors.

—Dr. Warren describes an interesting case, in which he made a permanent opening in the stomach of a man 56 years old, with a rapidly progressing cancer of the œsophagus. The patient lived for four months after the operation. One of the most interesting features of the treatment was the attempt to fit into the opening in the stomach and abdominal wall a pessary which would prevent leakage of the contents of the stomach; and the suggestion of an operation to make a valve-like fold of mucous membrane, to hang over the orifice, such as existed in the well-known case of Alexis St. Martin. Dr. Warren has succeeded in making a fistula in the stomach of a dog so protected, and is engaged in further experiments in this direction.

Correspondence.

Twins, One of Each Sex.

Ed. Med. and Surg. Reporter:

Sir:—The following question was propounded to me: "In cases of twins, one being a male, the other a female, is the female necessarily or frequently barren?" I answered in the negative. My questioner then wished to know whence originated the idea that in lower animals—citing the cow as an example—such was the case, and referred to Webster's definition of "free-martin." Can you, or any of your readers, throw light on the subject? I do not believe any such idea, and so answered. Yours, etc.,

T. J. Happel, M.D.

Trenton, Tenn., Dec. 29, 1887.

[We agree with our correspondent in regard to this belief.—Editor Reporter.]

The Conjugal Question.

Ed. Med. and Surg. Reporter:

Sir:—The numerous facts and frank opinions expressed in the Reporter by various members of the medical profession—in response to your request for a free discussion of this subject—are creditable to their respective authors. With a hope to see it more fully agitated, I offer the following remarks.

There is probably no topic within the whole domain of medical science which is at once so delicate, and so vital for the members of the medical profession to fully consider, as the subject of the conjugal relation. There is nothing so conducive to the individual happiness or suffering of mankind as connubial or concubinal sexual intercourse.

Sexual intercourse was originally designed for the purpose of propagating the human race. Hence it is an imperious necessity to human life. With normal, connubial usages, it is the chief preserver of virtue, health and morality. Practiced promiscuously and lustfully, with concubinal usages, it is a chief promoter of vice, disease and sin, and the gratification of a passion, for which man will brave any danger, however great, to health and even life.

All men have a repugnance to referring to these matters; but it is our duty, as right thinking, progressive members of the noblest of all professions, to use our best endeavors to suppress an evil far more pernicious in its influence and effects upon mankind than any other of which we have any knowledge, namely, promiscuous and lustful sexual intercourse—concubinage.

Again, this evil is very great, in view of the fact that it is the channel through which three of the most destructive diseases to mankind, viz., syphilis, scrofulosis and tuberculosis are conveyed. The time will come, I firmly believe, when the pathologist will establish the fact in science, which practical experience already confirms, that syphilis, scrofulosis and tuberculosis are akin, and originate in impure sexual intercourse. When this fact is established, and our knowledge of the danger of impure sexual intercourse reaches its proper limits, we shall have an argument against it which will strengthen the hands of those who wage warfare against what is destructive to the bodies as well as to the souls of our fellow-men.

Yours truly,

William B. Dewees, M.D.

Salina, Kansas, Dec. 29, 1887.

A Bad Burn.

Ed. Med. and Surg. Reporter:

Sir:—Mrs. N., age 67, on Nov. 15, 1887, accidentally put her right foot into a vessel of scalding water; when she removed her slipper and stocking, the integument came off of her foot and leg to about six inches above the ankle. I was not called until the 18th, when I found her suffering a great deal, and the wound discharging considerably. She had applied linseed oil and lime-water. On the 22d, I dressed the wound with a powder of subnitrate of bismuth and sulphate of morphia for twenty-four hours. The wound then looked better, and I renewed the use of linseed oil and lime-water. The wound progressed nicely until the morning of Dec. 20, when I found the foot and ankle red and œdematous. The woman's pulse was 110, her temperature 101°, with every evidence that I had a case of erysipelas to deal with. I now gave her:

Tr. ferri chlor.....f℥iss
Tr. digital.....f℥ss
M. Sig.—Cochl. parv. t. d. in half a tumblerful of water.

I also ordered a teaspoonful of sulphate of magnesia to be given every three hours until the bowels moved freely.

By the evening of the next day all the swelling and redness had disappeared, and the case is now recovering nicely.

Yours truly, G. G. Morris, M.D.

708 13th Street, N. W., Washington, D.C.

Jan. 9, 1887.

Ed. Med. and Surg. Reporter:

Sir :—I send you a recipe from a work entitled "Pharmacopœia Officinalis and Extemporanea; or, A Complete English Dispensatory," in two parts, theoretical and practical; printed in London, in 1741. There are many other recipes of similar character; and some still more disgusting. I copy exactly as given:

Vinum Millepedum,
Hog-lice Wine.

Take hog-lice, half a pound, put them alive into two pounds of white port wine, and after some days infusion strain and press out very hard; then put in saffron two drachms, salt of steel one drachm, and salt of amber two scruples, and after three or four days strain and filter for use. This is an admirable medicine against the jaundice, dropsy or any cachectic habit. It greatly deterges all the viscera, and throws off a great deal of superfluous humors by urine. It may be given twice a day, two ounces at a time.

I send an extract from a small work, entitled "Blair on the Grave." I copied it about forty-eight years ago. Never could obtain the book since, and never met with any person who ever saw it, though I have inquired of many. You might find use for it in giving some eminent deceased "Son of Esculapius" a proper obituary notice:

"Here the great masters of the healing art,
These mighty mock defrauders of the tomb,
Spite of their juleps and catholicons,
Resign to fate proud Esculapius' son.
Where are thy boasted implements of art,
And all thy well-crammed magazines of health?
Nor hill, nor vale, as far as ship could go,
Nor margin of the gravel-bottomed brook,
Escaped thy rifling hand; from stubborn shrubs
Thou wrung'st their shy, retiring virtues out,
And vexed them in the fire; nor fly, nor insect,
Nor writhy snake, escaped thy deep research.
But why this apparatus, why thy cost?
Tell us, thou doughty keeper from the grave,
Where are thy recipies and cordials now,
With the long list of vouchers for thy cures?
Alas! thou speakest not. The bold impostor
Looks not more silly when the cheat's found out."

Yours truly,

John C. Richards.

Philipsburg, Pa., Jan. 7, 1888.

—Women doctors and missionary doctors in the northwest of India and of Oude are coming prominently into notice. Nearly 72,000 cases were treated at eleven missionary dispensaries, and 11,000 women sought relief at Mrs. Wilson's dispensary, at Agra; 10,850 women and children were treated at the Thompson dispensary, at Agra; and the doctor in charge successfully performed some very important surgical operations.

Notes and Comments.

Childbirth in a Railway Car.

Dr. William Osler narrates the following remarkable story in the *Canada Medical and Surgical Journal*, January, 1888:

"Dr. Parvin's paper on injuries to the fœtus (read before the Philadelphia County Medical Society, Oct. 26, 1887) reminds me of an interesting experience which I had in the Northwest in 1886, which is worth placing on record. Mr. Fred. Brydges had kindly met our party at the Portage to take us over the Manitoba and Northwestern Road, and he mentioned that, two days before, a woman, while in the water-closet on the train, had given birth to a child, which had dropped to the track and had been found alive some time after. I was so incredulous that he ordered the conductor to stop the train at the station to which the woman had been taken, that I might see her and corroborate the story. I found mother and child in the care of the station-master's wife, and obtained the following history: She was aged about 28, well developed, of medium size, and had had two previous labors, which were not difficult. She had expected her confinement in a week or ten days, and had got on the train to go to see her husband, who was working "down the track." Having a slight diarrhœa, she went to the water-closet, and while on the seat labor-pains came on, and the child dropped from her. Hearing a noise and groaning, the conductor forced open the door and found the woman on the floor in an exhausted condition, with just strength enough to tell him that the baby was somewhere on the track, and to ask him to stop the train, which was running at the rate of about twenty miles an hour. The baby was found alive on the side of the track a mile or more away, and with the mother was left at the station where I saw her. She lost a good deal of blood, and the placenta was not delivered for some hours. I saw no reason to doubt the truthfulness of the woman's story, and the baby presented its own evidences in the form of a large bruise on the side of the head, another on the shoulder, and a third on the right knee. It had probably fallen between the ties on the sand, and clear of the rail, which I found, on examination of the position of the hole in the closet, was quite possible."

Syphilis Communicated By Tattooing.

In the *British Medical Journal*, December 10, 1887, A. Porter, surgeon to 1st

Battalion Middlesex Regiment, reports that Lance-Corporal B. was admitted into the station hospital, Dover, in 1886, suffering from two ulcers on the left forearm.

A week prior to admission his forearm, at the site of the ulcers, was tattooed by a comrade who had been discharged from hospital about a fortnight previously, where he had been a patient, suffering from a well marked attack of syphilis. The ulcers, two in number, were somewhat crescentic in shape, had each a diameter about the size of a florin, and were slightly blue in color from the staining of the Indian ink. They did not show any tendency to heal, and looked like chancres. The glands in the axilla became indurated and enlarged. Eight weeks after his admission a copious rash of a specific character appeared over his body.

On questioning the patient closely, the doctor found that during the process of being tattooed, the operator spat on the patient's arm and then rubbed it, in order to remove the blood which flowed at each puncture of the needle. As the operator had recently suffered from an attack of syphilis, the presumption is that the virus was conveyed to Lance-Corporal B.'s arm through the saliva of the tattooer. There was no evidence to show that Lance-Corporal B. ever had a primary sore prior to this. The usual treatment for syphilis was adopted; the eruption soon disappeared, but the ulcers were long in healing.

The Influence of Heredity upon Deformities and Defects.

The *British Medical Journal* says that some interesting observations bearing upon intermarriage and the recurrence or exaggeration of hereditary defects were brought before the Clinical Society recently, when Mr. Clement Lucas read a paper on "The Congenital Absence of an Upper Lateral Incisor Tooth as a Forerunner of Hare-lip and Cleft-palate." It is now very generally recognized that a defect from arrest of development in any part is liable to be repeated again and again, in succeeding generations, in spite of the introduction of new blood at each marriage. In illustration of this Mr. Lucas referred to a former observation of his, that among eighty descendants of a woman who had supernumerary digits, thirty per cent. presented a similar deformity. He also alluded to the case of a woman who married after having been successfully operated upon for cleft-palate and hare-lip; two of her six children presented a deformity similar to that of the mother. He now wishes us to go a step further, and detect a deformity, as it were, in an initial stage. He brought forward three cases to prove that a tendency to the congenital absence of a lateral incisor tooth might be transmitted as such, or might become the parent of hare-lip or cleft-palate. The absence of this tooth, it was explained, indicated an arrest of development along a particular line, which might in a future generation extend either to the lip or palate. Dr. Goodhart showed at the same meeting five children of one family, all of whom had nystagmus and staggering gait. The parents were first cousins, and there had been a former marriage of cousins on the mother's side, whilst on the father's side several relatives were deaf.

Deodorants for Iodoform.

Oil of turpentine has been recommended as a very efficient deodorant for the hands or for utensils, after they have come in contact with iodoform. They are first thoroughly rubbed with oil of turpentine, and, after about half a minute, washed with soap or soap spirit. It is also asserted that a watery solution of tannic acid, which leaves no odor of its own, destroys that of iodoform immediately, and can be washed off at once.

Pruritus Ani.

Dr. W. Mitchell Banks writes to the *Liverpool Med. Chir. Journal:* "I have been rather struck with the frequency of pruritus among the better classes of society as compared with the hospital classes. Out of 4000 cases occurring at St. Mark's Hospital in London, under the care of Mr. Allingham, only 180 were cases of pruritus. And we may be sure that a very large proportion of all the cases in London would be sure to find their way to a special hospital. I see plenty of cases of piles and fistula at the Liverpool Royal Infirmary, but I cannot get hold of a genuine good case of pruritus, whereas in private practice they are by no means uncommon. Cleanliness then can have nothing much to do with it in point of causation. Again, while probably showing a predilection for those who eat and drink too much, it assails people of very different appearance and habits. I cannot help thinking that it is in many essentially a gouty condition, and I found a course of Homburg do one patient great good—indeed it practically cured her, after everything else had failed. There is a method of treatment which I do not think is spoken of in books, but which I have tried

in two or three cases with great success. This consists in anæsthetizing the patient, and then with the big bulb of a thermo-cautery, heated to a white heat, lightly running over the whole affected surface, so as to produce a superficial burn. This seems a rather severe remedy, but then the disease is sometimes a very dreadful one, and makes the lives of its victims almost intolerable. Now, the look of the cautery is much worse than the reality, and a bit of lint kept moist with a solution of carbonate of soda soon takes the smarting away. I do not know if others have tried this plan, but it is an excellent one, and may be resorted to with tolerable confidence in aggravated cases. Deep cauterization is not required, merely a superficial frizzling."

Albuminuria from Irritating the Pneumogastric Nerve.

At a meeting of the Biological Society of Paris, MM. Arthraud and Butte demonstrated that lesions of the peripheral termination of the vagus nerve, produced by injections of lycopodium powder suspended in water, occasioned a nephritis with albuminuria, which developed slowly.

In a new note by M. Raymond, these experimenters announce that analogous results are obtained by the injection into the pneumogastric of an irritant liquid, such as very dilute croton oil. In this latter case the progress of the disease is very rapid, and hemorrhages occur in the skin, muscles and digestive apparatus. The nephritis which arises is diffuse.—*Bulletin Médical*, Dec. 7, 1887.

For Toothache.

Alcoholic ext. of opium,
Powdered camphor,
Balsam of Peru....of each 7½ grains
Mastic.....15 grains
Chloroform .....2½ drachms.

M.—Moisten a pledget of absorbent cotton with the liquid, and insert it in the cavity of the painful tooth.—*Union Médical.*

A Vesical Calculus with an Unusual Nucleus.

Dr. Lewis W. Rose, in a communication to the *Medical Record*, Dec. 17, 1887, reports the case of a man 58 years old, who came under his care suffering from urethral stricture and chronic cystitis. The stricture was cured by the introduction of sounds, and the urethra dilated so that a No. 19 English was readily passed. A stone having been detected on November 9, a drachm of four per cent. solution of cocaine was injected deep into the urethra, and a Bigelow lithotrite passed into the bladder. A mass about one inch in diameter was seized and crushed. Much difficulty was experienced in withdrawing the instrument. After half an hour of careful and patient manipulation, a leather shoestring, ten inches in length, was extracted, with but little discomfort to the patient. The string was massed between the blades of the lithotrite, and incrusted with phosphatic deposit. The patient denies any knowledge of how the string came into the bladder. He always enjoyed having sounds passed, and several times experienced sexual excitement during their introduction. At present he is progressing favorably.

A somewhat similar case was recently reported to the Academy of Surgery of Philadelphia, by Prof. S. W. Gross; but in his case the nucleus of the calculus was a fragment of a ligature, about an inch in length, which had remained in the bladder following an operation by a German surgeon.

Pyridin as a Heart Stimulant.

In the *Deutsche Medizinal-Zeitung*, November 24, 1887, it is stated that de Renzi (*Riv. clin. e terap.*, No. 3, 1887) from practical observation of seven patients in his clinic, has come to the following results:

1. Pyridin taken internally, beginning in doses of 6–10 drops in water daily, is well borne by patients, and this dose can by gradually increased up to 25 drops a day and over. 2. It markedly increases the power of the cardiac systole and diminishes the sensation of oppression and anxiety. One can also judge objectively of the more energetic systole of the heart through the stronger impulse of the latter. 3. The number of systoles diminishes after the use of pyridin correspondingly with the number of respirations. 4. By the use of pyridin the arterial pressure is raised, as was proved by the sphygmomanometer. Tracings also show that the pulse is rendered more regular. 6. It disposes of attacks of angina more quickly and more completely than any other remedy. It shows itself active in asystole, and that more quickly than digitalis, whose cumulative action, moreover, is avoided.

Formula for Creasote in Phthisis.

The following is Huchard's formula:

℞ Creasoti,
Iodoformi,
Pulv. benzoini,
Balsam. Peruv.....āā gr. ¾.

M. S.—For one pill. One or two to be taken at each meal.—*Revue de Clin. et de Thérapeutique.*

Fatty Degeneration of the Heart from Intra-Abdominal Pressure.

At the meeting of the Pathological Society of London, on November 8, 1887, Dr. Bedford Fenwick (*Lancet*, December 10, 1887) read a paper on cardiac degeneration due to abdominal disease. He related the case of a woman, forty-five years old, who had been married twenty-two years. She presented a uniformly distended abdomen; the heart sounds were dull. She was operated upon, and an ovarian tumor, weighing twenty-two pounds after all the fluid had been discharged, was removed. The wound of operation healed by first intention, but on the eleventh day the patient became very ill and peritonitis set in, followed by death on the twelfth day. The heart muscle was pale, yellow, soft, and friable; the wall of the right ventricle was very thin, but the wall of the left ventricle was of natural thickness. Microscopic sections showed fatty infiltration and degeneration of the heart muscle. He believed that such a condition could cause rapid collapse and death, and that it was, in fact, the pathology of twenty-two fatal cases in which the general condition was well marked. He suggested that the effects of direct pressure were the probable causes of the degenerative change, which, he said, was proportional to the duration and size of the abdominal mass; such a physical explanation being obvious, there was no need to invoke more obscure agencies. The majority of cases occurred under the age of fifty, and yet fatty degeneration of the ordinary kind was most frequent in males above that age.

Naphthol as an Antiseptic.

M. Bouchard, in *Comptes Rend.*, gives his experience with this substance and claims that Beta naphtol is absolutely safe in any form it is likely to be administered. Experiments on animals prove conclusively that it would require nearly one half pound of it taken internally to produce fatal results on a healthy person weighing one hundred and fifty pounds. When injected into the veins of animals as a one per cent. solution, the amount to produce fatality was equal to 400 grains for an adult of one hundred and fifty pounds. Ten grains in a quart of water will prevent the growth of any organisms. It has five times the antiseptic power of carbolic acid, four times that of creosote, three times that of iodoform, five times that of iodol, four times that of naphtaline, but has only $\frac{1}{20}$ the destructive energy of biniodide of mercury.—*Pharmaceutical Record.*

NEWS.

—The hundredth birthday of the celebrated anatomist and physiologist, Johann Evangeliste Purkinje, has just been celebrated at Breslau.

—A man is said to have died in Cincinnati recently for the want of medicine, which could not be compounded because the druggist was unable to decipher the prescription in the case.

—In Paris, during the week ending December 10, 1887, there were 1209 births. Of these 622 were males, and 587 were females. Of the whole number, 335—more than one-fourth—were illegitimate.

—The late Dr. James R. Nichols, of Haverhill, Mass., was a well-known and much-esteemed citizen, distinguished for his public spirit, his scientific achievements, and his capacity as a business man. He was an editor, a chemist, and a railroad manager, and had filled most all the positions creditably.

—Where ice cannot be procured, water may be cooled by wrapping the pitcher containing it in a towel of loose texture which has been previously impregnated with ammonium nitrate (*and dried*), and moistening this with water. The same towel may be used repeatedly, being dried thoroughly beforehand each time.—*Phar. Era.*

—A simple method of preserving fresh fruit is to place it in a wide-mouth, glass-stoppered bottle with a little chloroform. The stopper of the bottle should be greased with a little petrolatum to make it air-tight. A drachm of chloroform suffices for a quart bottle. The chloroform soon evaporates on exposure to the air, or is dissipated in cooking.—*Phar. Era.*

—In concluding a paper in *Science*, January 6, 1888, upon the question whether forests influence rainfall or not, Henry Gannett says: "It seems idle to discuss further the influence of forests upon rainfall from the economic point of view, as it is evidently too slight to be of the least practical importance. Man has not yet invented a method of controlling rainfall."

—The New York Academy of Medicine has just received a valuable addition to its library of 30,000 volumes in the shape of 6000 standard works. They are the bequest of Dr. Middleton Goldsmith, of Rutland, Vt., recently deceased, and came through Dr. John C. Peters, of New York, who for nearly half a century was a warm personal friend of Dr. Goldsmith.

—The President has sent to the Senate the nomination of Henry Leffmann, of Pennsylvania, to be Coiner of the Mint at Philadelphia. Dr. Henry Leffmann was born in this city, forty years ago, and is a graduate of the Central High School and of the Jefferson College. He is Professor of Chemistry in the Wagner Free Institute of Science, and an honorary member of the State Board of Agriculture.

—Mr. Ford H. Carruth, the "funny man" of the Chicago *Tribune*, occupies more than half a column of the issue of that newspaper for January 6, with a stricture upon physicians, and especially upon young physicians. The comments he makes are not very amusing, and they are very unjust. He must have been unfortunate in his acquaintance with doctors; and if the medical men in Dakota find out what he says about them, it will try their benevolence pretty severely if he ever falls sick in their part of the country.

—The whiskey detective has, of late, been very busy in Toronto, and a large number of druggists have been brought before the police magistrate. In all instances in which convictions were obtained, a fine of $20 and costs was inflicted, and some parties, against whom two charges were made, were subjected to a second fine. We have always held that it would be better for druggists to abandon, completely, the sale of liquor, and we believe that in the long run it would pay. The methods pursued by the informer here were of a very questionable character and have called forth much indignation from druggists.—*Canadian Phar. Journal.*

—Several months ago a doctor went to Chicago and commenced the practice of medicine. He advertised extensively the cure of a special class of diseases, when the State Board of Health interfered and revoked the doctor's certificate. The doctor then commenced an action against the State Board in the Circuit Court. Recently, Judge Waterman decided the case, and declared the act of the State Board of Health unconstitutional. He said: "The right of a party charged with a punishable offence to notice of hearing is elementary, and one of the first rules necessary to the administration of justice. The defendant had a perfect constitutional right to advertise in the newspapers, and he cannot be deprived of it by any rule or regulation of the State Board of Health. This association, if its action was to be held legal in this case, could summarily try and punish for an alleged offence a brother practitioner without any notice whatever."

HUMOR.

A LITTLE BOY was taken sick for the first time, and the doctor, with much ceremony made him swallow a powder. "Papa, said the boy, a minute later, "ain't it time I was taking the *shot*, now?"—*Puck*

AN ambiguous compliment: "If you use my mixture once," said a patent-medicine man, "I'm sure you will never use any other." "No," was the reply, "I don't suppose I ever would."—*Judge.*

MACON (GA.) *Telegraph* says: They call it "Mind-cure" in Boston and "Voudooism" on the Southern plantations; but about the only differences is in the name and in the fact that the Voudoo charges less.

THE LONDON *Globe* says: It is comforting to find that the boiling point of "allylenedichlordibromide" is 190°, while that of "methylchlordibrompropylcarbinylchloride" is something between 140° and 145°.

A MATCH VENDER entered a butcher's shop, when the following brief dialogue was heard: "Vender—"Hello, chops! How's your liver to-day?" Chops—"Three cents a pound. How's your lights?"—*Lowell Citizen.*

A TEACHER said to a member of the State Board of Health who was investigating the condition of her room, "No, I haven't any ventilators: I don't see any use for them." "But how do you keep the air pure?" "Oh, I've got a thermometer."

REQUIRES PERSEVERANCE.—"Young man," said a cross old lady on a street car, "terbacker smoking makes me sick."

"It used to make me sick, too, ma'am," replied the young man, lighting a fresh cigar; "but, Lord, you'll get used to it after a while."—*New York Sun.*

HE COULDN'T AFFORD IT.—A mother was urging her son to purchase an overcoat and he was insisting that he could not afford one.

"Very well, then," said she, "you will get pneumonia, see if you don't."

"No," said he, "I won't get that either; I can't afford anything new."—*New York Sun.*

A MISER, troubled with heart-disease, finally decided to call a physician. After the preliminary examination the patient asked: "Doctor, how much is it going to cost?" "Not a sou." "Thanks; but you're too kind. I ought not to—" "O don't trouble yourself! Your heirs will see that I am paid."

A DOCTOR near Louisville, Ky., fell off his chair while taking a nap on the porch of his dwelling recently, and a pistol in his coat-

pocket was discharged, killing him almost instantly. The occurrence has awakened a strong feeling among the people of that vicinity against the practice of sleeping in chairs.

IT IS A WISE FATHER that knows his own child.—The *Pittsburgh Med. Review* says editorially: The March number of the *Review* contained a translation from the *Centralblatt für Gynecologie* of a case of tuberculosis of the peritoneum cured by laparotomy, which was performed by Dr. Poten, of Hamburg. In April the *Medical Record* printed the report, giving proper credit; and now the same article, retranslated into German, adorns the September issue of the *Centralblatt*, as a report by Dr. Poten, of Pittsburgh. The short sojourn of a few months in this country had so Americanized this assisted immigrant that he returned as a stranger to the place of his nativity.

OBITUARY.

DR. CYRUS N. BLOUNT.

Dr. Cyrus N. Blount died after a short illness at his home in Kokomo, Indiana, on Wednesday, December 28. Dr. Blount was born August 26, 1832. He was graduated in 1858, from Butler University, at Indianapolis, in which city he began the study of medicine. A few years afterward he took the degree of M.D. at the Jefferson Medical College, Philadelphia. He practiced his profession for eleven years at Tipton, Indiana, and for fifteen years at Hagerstown, Indiana. He removed to Kokomo, Indiana, in August, 1887, to accept a partnership with Dr. Armstrong, a leading physician of that place. As a practitioner of medicine Dr. Blount was highly successful, being a man of much more than ordinary ability and always genial and courteous toward his brother physicians, and ready to extend a helping hand to the younger men in the profession. He was an active member of the Indiana Medical Society, of the Eastern Indiana District Medical Society, and of the Wayne and Henry County Medical Societies. As an essayist Doctor Blount had few superiors, and he was a ready and apt speaker upon any subject. His character was thoroughly Christian, and no sacrifice was too great for him to make for the church he loved. He was a stanch advocate of the temperance cause.

Doctor Blount was twice married, his first wife who lived only a short time after her marriage, being a sister of Judge N. B. Taylor, of Indianapolis. Some years after her death, he married Miss Fannie A. Dyer, by whom he had three children. His wife and two sons survive him. J. N. S.

JOHN P. SEILER, M.D.

Dr. John P. Seiler died suddenly in Harrisburg, on January 5, 1888, at the age of 42. He made his regular calls on patients on Tuesday, but on Wednesday (January 11) was confined to the house by an attack of rheumatism, a disease to which he was subject. On Thursday morning he was found in a comatose state, and an hour later died. Dr. Seiler was a leading physician and surgeon, and his practice was extensive.

WESLEY M. CARPENTER, M.D.

Dr. Wesley M. Carpenter, Professor of Clinical Medicine in the University of the city of New York, was found dead in bed in his home in New York on Saturday, January 7. He had been a sufferer from heart disease for some time.

THOMAS WARDLE, M.D., D.D.S.

Dr. Thomas Wardle died in Philadelphia, on December 5, 1887, in the 69th year of his age.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Jan. 8, 1888, to Jan. 14, 1888:

Capt. Louis S. Tesson, Assistant Surgeon, relieved from duty at headquarters, Div. of the Missouri, and as Examiner of Recruits at Chicago, Ill., and ordered for duty as Post Surgeon at Watervliet Arsenal, N. Y., relieving Capt. Henry G. Burton, Assistant Surgeon, S. O. 5, A. G. O., Jan. 7, 1888.

Capt. Richard Barnett, Assistant Surgeon, ordered from further duty in Div. of the Atlantic, to duty at Fort Riley, Kan.; to take effect at the expiration of his present sick leave. S. O. 5, A. G. O., Jan. 7, 1888.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Jan. 14, 1888:

George Purnance, Surgeon, to proceed to Detroit, Mich., as inspector of unserviceable property. Jan. 11, 1888.

H. W. Austin, Surgeon, when relieved to proceed to Chicago, Ill., and assume charge of the Service. Jan. 12, 1888.

J. M. Gassaway, Surgeon, leave of absence extended fifteen days. Jan. 10, 1888.

C. B. Goldsborough, Surgeon, when relieved to proceed to New Orleans, La., and to assume charge of the Service. Jan. 12, 1888.

Fairfax Irwen, Surgeon, to proceed to Boston, Mass., and assume charge of the Service. Jan. 12, 1888.

H. R. Carter, Passed Assistant Surgeon, when relieved to proceed to Ship Island Quarantine, Miss., and assume temporary charge of the Service. Jan. 12, 1888.

P. M. Carrington, Assistant Surgeon, granted leave of absence for thirty days. Jan. 10, 1888.

WHOLE No. 1613.] JANUARY 28, 1888. [VOL. LVIII., No. 4.

PHYSICIANS.— American Lady wishes to take charge of Physician's House; fully competent, and willing to assist in office; unexceptional references. City or country. Address Mrs. S., care 501 Morris Avenue, Elizabeth, New Jersey.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

ATTEMPTED NEPHROLITHOTOMY; WOUND OF THE DIAPHRAGM; RECOVERY.

BY JOHN B. ROBERTS, M.D.,

Professor of Anatomy and Surgery in the Philadelphia Polyclinic.

I report the following case of attempted nephrolithotomy, which occurred, in the spring of 1886, in the person of a private patient at the Polyclinic Hospital, as a contribution to the literature of the subject; and because I believe it to have been the first case of the kind occurring in Philadelphia. Since the operation here reported, Dr. S. W. Gross has performed at the Jefferson College Hospital nephrolithotomy, and successfully extracted the calculus from the pelvis of the kidney.

S. B., aged 39, had for the last two years suffered with pain in the region of the left kidney, which had troubled him almost incessantly. He came to Philadelphia with the hope that some treatment might be instituted which would relieve him from his suffering, which had failed to yield to the ordinary methods of treatment. After careful examination of the case, and consultation with the other surgeons of the Polyclinic Hospital, I determined that there was sufficient reason to believe the pain due to renal calculus, and, therefore, that an exploratory operation in the lumbar region was justified. Accordingly, on May 20, 1886, I made an incision in the left loin, and at once came upon the left kidney. In order to get more room, it was determined to cut a few muscular fibres which extended across the upper angle of the wound a little distance below the surface. Accordingly, they were divided and instantly the sucking of a large quantity of air into the pleural cavity showed that these fibres were a portion of the attachment of the diaphragm to the posterior wall of the abdominal cavity. The opening, which was a very small one, was of course close to the vertebræ. The tissue was not recognized as a part of the diaphragm before being cut, because it was posterior to the bulging portion of the diaphragm which was seen at the bottom of the wound. The opening so made was closed by silk sutures with no other difficulty than that it was difficult to get the sutures to draw the edges of the orifice close together on account of the muscular fibres being tensely attached to the bone. It would have been very easy to close a similar puncture situated further out in the flaccid portion of the muscle.

The surface of the kidney was felt with the tip of my finger without discovering any sign of stone. I then thrust a long needle in various directions through the kidney structure towards the calices without coming in contact with any hard substance. The operation was an exceedingly easy one in all its details, with the exception above mentioned of the trouble experienced in sewing up the small opening in the diaphragm. A small aseptic sponge, previously dusted with iodoform, and with a short string attached to it, was thrust into the wound against the injured diaphragm. The external incision was then closed with five wire sutures, the string attached to the sponge left hanging from the wound, and the parts dressed with carbolized oil and a bandage. The following day the wound was dressed with sublimate cotton, and on the third day the sponge was removed, at which time a large portion of the external wound had united by first intention. Subsequently, there was some suppuration in the

wound, and it was syringed with a solution of bichloride of mercury, 1 to 1000. The temperature which had been comparatively high for a day or two previous to the beginning of the syringing, soon fell, although it did not come down to the normal for a number of days. For a few hours after the operation, the urine was somewhat bloodstained, but soon became of normal color. On the tenth day after the operation, catheterization drew off a pint of dark-colored urine, which he was unable to pass naturally. The wound was not being dressed at this time with carbolic acid, nor had it been since the first day, as the mercurial dressing had been employed in connection with the iodoform powder. As time went on the patient became anæmic: the portion of the wound which had not healed became sluggish in appearance; the man's general condition deteriorated and his appetite became poor. About a month after operation, he complained of considerable pain deep in the wound, which made it impossible for him to lie comfortably in bed. This was particularly noticeable because the pain from which he suffered previous to the time of the operation had been greatly alleviated by that procedure, although no stone had been found in the kidney. The mere fact of operation had made him much more comfortable, although it was difficult for me to understand why so much relief was given without a more patent cause having been removed. Subsequent to the advent of the deep pain just mentioned, there was suddenly a discharge from the wound of a large quantity of watery and purulent fluid which soaked entirely through the dressing and clothing. This material was examined to see if it contained urine, but the result was negative. It was, I believe, considered by Dr. W. B. Hopkins, who had charge of the case at that time for me, to be due to the rupture of a kidney cyst. Although this fluid apparently contained no urine at first, the discharge which continued soon assumed a urinous odor. From this time the patient gradually improved, and, after a stay of about two months in the hospital, returned home. There was about an eighth of an inch of uncicatrized wound from which there was a slight discharge of pus. I heard from him a number of times after his return to the country, but the reports were never very favorable. He was well enough to be up and about and able to go out, but did not become strong and vigorous, nor did the wound entirely heal. At times there was a good deal of pain in and around the wound. After a few months' time, he gradually failed and died with no other diagnosis of the cause of the pain being made; and, as far as I know, no autopsy was made.

The case is reported as I have said above, simply as a contribution to renal surgery, and to show with what ease the diaphragm may be punctured by an incision which apparently is far from it, because of the way in which the posterior border of the diaphragm takes its origin along the spinal column. The case is also important, I think, as showing how innocuous such a wound of the diaphragm is if promptly sutured and treated in an antiseptic manner.

For the notes of the case, I am indebted to the House Surgeon at the Polyclinic Hospital, Dr. W. H. Hale.

1627 Walnut St., Philadelphia.

THE TREATMENT OF DIPHTHERIA.

BY JOHN PIRNAT, M.D.,
EVANSVILLE, IND.

I would like to give to the readers of the REPORTER my treatment of diphtheria. My formula, which was published a year ago in my pamphlet on diphtheria, is—

℞ Potassii chlorati.....3v
Calcii sulphurati.....3j
Magnesiæ phosphatis.....3j
Pulv. sacchari aromat.....q.s. ad ℥ij

Misce, et fiatpulvis subtilissime. S.—Dose for an adult, sixteen grains every two or three hours; for a child of six years, eight grains.

I have prepared this formula myself for the last twelve years by rubbing the different ingredients into an impalpable powder, adding the aromatic sugar last, thus making it of quick absorption, and not unpleasant to the taste. This is an important point with children and infants. If the prescription is sent to a drug store, the ingredients will be put together into the mortar, rubbed for a while, and divided into powders, which will be not only unwholesome, but at the same time disagreeable to take.

The second preparation which I use is the so-called "anti-diphtheriticum," composed of C. P. naphthalin, tincture of pine gum, and compound elixir of orange peel. This is a private formula of my friend Dr. L. Dohme, and is given to the profession at at my own instigation. It is superior to my preparation, and almost specific in this disease. Although it is a proprietary medicine, I find it no more unprofessional to prescribe than Dr. E. Williams's improved brown citrine ointment, which is a valuable remedy for chronic ophthalmia and phlyctenular con-

junctivitis, and sold only by Mr. Fennel, of Cincinnati, as "Prof. E. Williams's private formula," at four dollars per pound. I hope the esteemed Professor will give this excellent formula and its therapeutic uses, to the profession, as a remembrance of his name for time to come.

Although I have implicit confidence in these two preparations as curatives in diphtheria, still in all cases of severe character, or with complications, I resort from the very start to other adjuncts, as a safeguard. For instance, if malaria is suspected, quiniæ sulphas, tinct. ferri chloridi, and glycerine, in proportionate doses, are given between the other remedies. In extensive formation of plastic exudation, or if the membrane is dark grayish looking, and the patient old enough, I order the following preparation as a gargle:

℞ Acid. carbol ..... f℥ss
Ext. eucalypti glob. fl..... f℥x
Ext. pini Canad..... f℥ij
Glycerinæ..... f℥ij
Aquæ..... q.s. ad f℥viij
M. S.—Gargle well every two hours, for ten minutes each time, before taking the medicine.

For children:

℞ Tripsin..... ℥ss
Sodæ bicarbon..... ℥ss
Hydrarg. chloridi corros..... gr. ¼
Glycerinæ..... f℥j
Aquæ rosæ..... f℥vij
M. ft. sol. S.—Spray every time before medicine is given.

Or,

℞ Acidi lactici..... f℥ij
Hydrarg. chloridi corros..... gr. ss
Glycerinæ..... f℥ij
Aquæ..... q.s ad f℥iv
M. ft. sol. S.—Spray each time before giving the medicine, applying a cloth dipped in cold vinegar (not too wet) to the neck.

Of late years my rule in treating cases of diphtheria is to give the diphtheritic powders and the "anti-diphtheriticum" every hour and a half in alternation, day and night, until the diphtheritic membrane is entirely gone; then every two or three hours, for some days, until the patient is quite well; and then, if it is necessary, I prescribe either elix. phosph. iron, quinia and strychnia, or liq. potas. arsenitis, three times a day after meals. In cases of scrofulous or syphilitic taint, I order syr. ferri iodidi, or liq. potas. arseniti, to be taken after meals, and a cod-liver oil emulsion before meals.

In this city of about 40,000 inhabitants, we have had plenty of diphtheria within the last three years, and my success in treating it has been such that I have recorded only four deaths from this disease in the last twelve years; and in these cases the disease was complicated with membranous croup. It may be that I was lucky enough to meet only with benign cases. In conclusion, let me state that either the first or the second preparation will act as a preventive; and that, if it is given three or four times a day to children, where a malignant case exists, one need not be afraid of any trouble—at least this has been my experience thus far.

THE NATURE AND CURE OF SYPHILIS.

BY P. P. QUACKENBOSS, CHEMIST,
PHILADELPHIA, PA.

In the initial lesion of syphilis we find the skin or epidermis presenting an appearance very similar to that of a burn: we find the cellular structure disintegrated, and the virus penetrating into the lymphatic circulation rapidly. If, however, the virus is destroyed before this stage is reached, no evil effects are perceptible; but let it go on for a few hours, putrefactive matter accumulates, is absorbed, and carried into the circulation throughout the whole body by natural processes, which are well understood, creating those septicæmic conditions we are familiar with.

On looking for something to act as an example to illustrate germ-growth, nothing presents itself better than the Torula cerivisiæ, or yeast-plant, in its action upon "wort" in making beer. After the different constituents are mechanically put together, in proper proportions, the yeast is added, the conditions of heat and moisture secured and graded, and the first stage of growth is inaugurated. This demands one of the original elements for its existence, breaks up the chemical combination present, and produces a different one. These germs pass in turn through the different stages of access, accentuation, attenuation, and putrefaction; and if the same yeast is used through successive stages, it totally loses vitality, a fact well known to brewers. This is the basis for Pasteur's culture of bacterial growth, and this will help us to understand the different stages of the disease under discussion.

To make the virus of syphilis visible, we apply a solution of bichloride of mercury to the surface of the ulcer, in order to coagulate the albumin. Then wash it with a saturated solution of hyposulphite of soda to blacken it, in order to distinguish it from the cuticle. Tearing this off with a small for-

ceps and placing it upon a microscopic slide, we find underneath it a thin viscid fluid containing the cause of the trouble, as well as the excrementitial or putrefactive matter.

If we attempt to exterminate this growth by the old practice of burning, we find it too deep-seated to be reached with the limited means at our command, in nitric acid or its various compounds, and we only succeed in destroying a portion of it, and that the least active. If, however, we use one of the salts of potash, we can dissolve a part of the tissue surrounding these growths, and, following it with a solution of sodium salts, we can restore the tissue to nearly its normal condition; and if, during this change, the micro-organisms could be exposed to a dry air heated to 160° or over, they would be killed at once. So I am led to believe that, if these conditions can be arranged, the disease can be controlled.

In the past ages a system has been pursued (by physicians that depended upon that eminent empiric Paracelsus for their ideas) which maintained the use of mercury in combination with certain salts as a germicide. In view of the well known septicæmic action of any of these compounds, it is like a policeman shooting pistol balls into a crowd of ten thousand innocent men in order to hit one thief. Other practitioners have depended upon iodide of potassium—a combination of slow dissolution—together with certain alterative medicines, which certainly have an effect upon animal tissue under normal conditions, but under diseased ones may not act properly. Still, if we follow them chemically, we observe that the combination breaks up, and the iodine, being freed from the carbonate of potassa, seizes upon the proper chemical constituent that may be in juxtaposition to it, just as it does in the laboratory.

Iodine combines by natural affinity with an alkali, and of course seizes the most soluble one in the skin or in the mucous membrane, thus in its turn destroying the combination then existing, and, let us say, depositing a film of iodide of potash, in place of the carbon and potassium that already existed, which has to be eliminated in the regular method and time. What proof have we that, therefore, it destroys putrefactive matter in preference to live tissue?

We know that carbon gives stability to potassium and sodium, whether combined in the skin or not, governed solely by the amount contained in each. If, therefore, we find the cellular structure of skin broken down by the abstraction of some element by the germ, and discover that by treatment with a mixture of these salts, together with a germicide such as sulphur, the germ is killed, while the cellular structure is either restored, or, if taken in time, is prevented from destructive action, we are led to believe that those elements are demanded. Therefore, I would suggest the employment of aperient waters containing the elements of carbon, sulphur, potassium, and sodium, etc.; and, as the Turkish bath offers the most feasible method of exciting the skin to an abnormal excretory action, and at the same time exposing the germ to a heat that will kill it, say 170°, therefore add a Turkish, not Russian, bath at least three times a week, at the discretion of the physician. In experimenting, I have found that a hot application of a saturated solution of sodium hyposulphite will absolutely kill the virus in its early stages, and prevent inoculation, if applied within an hour after infection. The effect is enhanced by a previous use of carbonate of potassium in solution. In view of these facts, we have every chemical reason for believing that, in due time, the whole germ-growth can be exhausted. But patience and perseverance are both necessary factors in this method.

IMPERFECT PREPARATION FOR THE PRACTICE OF MEDICINE.

BY ENOS T. BLACKWELL, M.D.,
CEDARVILLE, N. J.

Much has been written in this country upon the rapid manner in which very young persons of limited education and moderate capacities are transformed into doctors, to whom are entrusted matters of life and death, affecting the people among whom they locate. When we reflect upon the acquisitions of those who teach, medical and literary, and realize that they must know how ill prepared are many of the newly-made professionals to sustain themselves respectably, either as regards the work done by them, or as social factors in their several localities, one can but wonder and deplore. It would seem that the blush of shame must often mantle a professor's cheek, as he sees the practical results of imperfect teaching in the creation of so-called "graduates," who have "small Latin and less Greek," and no competent knowledge of their mother tongue. The medicaments and prescriptions of some of these neophytes are such as to make a qualified pharmacist wonder and lament. The following case came under my own notice:

A young man, who had attained a working faculty in a pursuit where some knowledge of letters would be acquired by the dullest, in an evil hour, as it seems to me, bethought him to prepare for the practice of medicine. Procuring the catalogue of a prominent New York medical college, and such notions of the art of healing as he could gather without a preceptor, he entered its walls in the capacity of a student. Disposing of his time as circumstances dictated, he entered for a second course, falsely registering as having studied under a preceptor; and in due time was dismissed with a suave bow, and "*vale doctor.*" Settling down to practice, this "*virum probum*" assumed huge proportions, and among other wonders undertook the cure of cancers—gravely attending daily upon cases in the last stages, and sapiently dressing the ulcerated surfaces with a solution of carbolic acid, and applying fresh bandages. The following are specimens of his prescriptions:

1. ℞ Port vinum.....4 oz.
Dr. ——

2. ℞ Liquor potass iodid.....80 minims
Potass iodid.....16 grains
Iodid puri..... 3 grains
Syrup flui auratium ..... 2 oz.
Half-teaspoonful 3 times a day. Dr. ——

3. ℞ Calomel..... 2 grains
Santonin.....10 grains
Divide into 2 powders, and give one night and morning. Dr. ——

The following prescription was one which he greatly lauded. It was French, and was ordered for a woman in the last stages of phthisis pulmonalis:

4. ℞ Pure creasote.....10 parts
Compound tincture gentian...30 parts
Alcohol.....150 parts
The whole to measure one pint.
Dose.—One to five tablespoonfuls. (!)

If the poor lady for whom the prescription was ordered took a tablespoonful, which was the minimum dose (which was allowed to pass by the druggist), she swallowed creasote, 12½ minims; comp. tincture of gentian, 38 minims; and alcohol, 3 fluid drachms, 9 minims. Had she taken the maximum dose ordered, she would have received a draught containing about 63 minims of creasote, 3 fluid drachms of compound tincture of gentian, and 2 fluid ounces of alcohol.

It is needless to add that the dose taken caused great burning in the throat, and it is fearful to contemplate the misery that would have followed the ingestion of the larger quantity.

With reference to this man's prescriptions of santonin, I do not know what were the ages of the children to whom they were given; but as I was informed by the parents of some that their doctor was "death on worms," and also on the patients, I infer that the amount exhibited was much too large. This opinion is also sustained by an analysis of the papers. Prescription No. 3 calls for five grains of santonin, night and morning—ten grains within about twelve hours. Another of his prescriptions ordered twenty grains in twelve hours. Estimating the ages of the children at from five to ten years, we can easily agree with the parents that the medicine was "too strong."

Whatever may be the merit of the average student, graduated after attendance on two courses of lectures, with the period of study often less than three years, the above case is sufficient to arouse inquiry why this haste to dismiss youths only half equipped for their serious and responsible work? The crowded rooms of some medical schools would seem to indicate that it is to make room for the fresh recruits who throng their doors.

However humiliating the defects of the raw disciples may be to the scientific brothers who have toiled long and anxiously to fit themselves for their responsible duties, the methods employed by the fresh aspirants to gain notice and patronage are equally obnoxious and lamentable. Practices at variance with established codes of ethics are resorted to, and *esprit de corps* seems to be quite lost sight of. These are the doctors whose patients are afflicted with most difficult and fatal diseases; who declare that to be diphtheria which to the eye of honest practitioners is herpetic sore throat, or simple angina; who diagnosticate gout as senile gangrene, and ephemeral fever as typhoid fever; who frequently declare their patients at the point of death, and needing the most assiduous and constant attention, so that when recovery takes place the physician may be glorified—nay, may even glorify himself—and, like the frog in the fable, swell himself to vast dimensions.

With such gaseous inflation the aspiring doctor's popularity soars for a season, and when its means of expansion are exhausted, it sinks and dies, only to be succeeded by other bubbles of a similar character. Sufferers following these misleading pretenders are like other silly mortals who follow *ignes fatui*, which they never reach, and which are unsubstantial and elusive in their nature.

FORMS OF MALARIAL FEVER OBSERVED IN ELEVATED REGIONS; WITH REMARKS ON THE COMPARATIVE UTILITY OF PREPARED LEMON-JUICE AND QUININE IN THEIR TREATMENT.

BY L. HUBER, M.D.,
ROCKY FORD, COLORADO.

The following cases are elaborated from notes recently taken, and present some interesting facts. The remarks upon the therapeutic agents, mainly relied upon in the treatment of these malarial diseases, are not generalized from these few cases, but embody the results of several years' experience with them, in the treatment of allied forms of fever. The use of prepared lemon-juice is not a new practice with the writer, and what he says embraces no hasty conclusions.

For convenience, the fever forms herein described are classified under two heads: *Irregular* forms and *continuous* types.

I. Irregular forms of Malarial Toxæmia, simulating spinal disease.

James D——, adult, has complained repeatedly of a more or less sudden attack, in which the muscles of the back of the neck, of the back itself and of the lower extremities would become rigid and painful. Simultaneously there would be fever symptoms, as burning of the skin, flushing of the face and injection of the eye. All these symptoms would develop daily at or about 6 P.M. During the night, and usually about 1 o'clock in the morning, there would be a copious perspiration.

When Mr. D—— applied to me I found his temperature sub-normal (97.3°), his pulse feeble, his tongue coated, his skin clammy and saffron-hued. It was in the morning, and I asked him to present himself in the evening, which he did, when I found the symptoms first described. His temperature was 102°, and his pulse 90. The midnight following, there was a copious sweat.

This periodicity of symptoms suggested strongly the malarial origin of his disorder; though he had not been out of this locality for a long time, where the elevation is 4000 feet above sea-level, and where there is a remarkably dry soil. Having been given quinine in full doses for over a week, I concluded to administer a remedy which deserves to be brought more fully to the notice of the profession, viz.: *prepared lemon-juice.* Note that I say *prepared lemon-juice.* Nearly every physician has some vague notion of the value of lemon-juice in the treatment of malarial toxæmia; there are few, however, who have any definite and adequate idea as to its best method of administration.

What I directed Mr. D—— to do applies to nearly all the cases which I think amenable to prepared lemon-juice. I ordered him to slice a good sized, fresh lemon into three pieces, rind and all, and after placing the fruit thus divided in a quart of water, to boil the quantity down to one-fourth of a quart, strain the syrupy liquid, and when cold, take it in a single dose. The best time for administration is early in the morning, upon an empty stomach. I rarely order more than one dose a day. Sometimes shortly before the evening meal I direct a second and smaller quantity to be taken.

This agent, thus prepared and administered, is highly efficacious in obscure and obstinate cases of malaria. With me it has become more popular than quinine, and has in many instances proved its usefulness. It is not an acid remedy, as many suppose, but an alkaline one. Some of its virtue must be due to the citric acid it contains, and this agent is broken up in the blood and converted in one or another salt.

To secure the highest efficacy of this antiperiodic requires persistency in some cases. It is my habit to keep up the daily morning dosage for a week. If the hepatic functions are deranged and tardy, I often precede its use with a mild laxative made of compound colocynth powder and nux vomica.

Allied to the case just described is that of Mrs. G——. I was summoned hastily to this patient one evening between 7 and 8 o'clock. I found her in more or less distress, complaining of pain in the back of the head, and in the neck, back and arms. Her speech was hesitating and slow; there was considerable motor excitement, confined mainly to the muscles of the upper extremities and face. The pulse was irregular and not, on an average, over 40; her temperature was subnormal (96.2°). I ordered a mustard bath for her feet, and mustard poultices over the back of her neck. Regarding the case as one of sudden congestion of the base of the brain and upper portion of the spinal cord, in which region a heavy dull pain was complained of, I had administered small but frequently repeated doses of ergotin and belladonna. In a reasonably short time the symptoms improved; and, by pushing the measures whenever the symptoms seemed about to recur, the patient was kept in a fairly comfortable condition. The next day the following pill was given:

℞ Quiniæ sulph.....℈j
Ergotin.....gr. iij
Ext. belladonnæ.....gr. ij
M. Ft. pil. No. x. Sig.—One every two hours.

Mrs. G—— then improved still more, and went about her usual pursuits. After several days she consulted me again, complaining of flushing of the face, headache and extreme nervousness. These symptoms regularly recurred about midday. I asked to see her about that time, which was allowed; and, in confirmation of my suspicion, I found, with other indications of a mild malarial paroxysm, a pulse of 93 and a temperature of 101.5°

This case becomes all the more interesting when the history of a previous accident to Mrs. G—— is related. Five years ago, while riding on horseback, the animal became unmanageable and pitched so severely that Mrs. G——'s impact with the saddle fractured the coccyx. Caries set in, and the case was terminated by a removal of the last segment of the vertebra. During this time she suffered from some degree of traumatic spinal meningitis, and later from excessive spinal irritation. However, for several years these conditions had improved, and she considered herself practically well.

After discovering what I strongly suspected to be a malarial paroxysm, I concluded to put Mrs. G—— on prepared lemon-juice. This was done, and with the happiest result. All the symptoms disappeared: the fever, headache, motor disturbance and general nervousness. With this direct and perfect eradication of all the outward signs by an agent known to possess anti-periodic qualities, but not known to have any virtues for symptoms having a different cause, I concluded that Mrs. G——'s case was simply another example of the irregular malarial fever more or less common to high altitudes.

This brings me to a point that I will mention, but not discuss, namely, that in Colorado and adjacent elevated countries the malarial poison is prone to affect the nerve-centres, more especially the spinal cord. It is my opinion, deduced from a series of observations, that so-called mountain-fever is a type of malarial fever, in which the poison implicates the spinal cord and the base of the brain. It is my belief, moreover, that quinine has few specific qualities for this type of fever. The remedy *par excellence* is yet to be brought forward. Mountain sage has a deserved local reputation. Further experience may prove the usefulness of prepared lemon-juice for these cases.

II. Regular forms seen in adults and children; the continuous type.

Mr. B.——, a laborer, principally engaged during the summer and fall in digging cisterns, applied to me for treatment. He complained of having a chill, great muscular soreness and weakness, headache, and want of appetite. Upon examination, I found his pulse 102 and his temperature 103.5°, with evident engorgement of the liver and a thickly coated tongue, the coating pretty uniformly distributed over the organ. I put him upon 5 grs. quiniæ sulph. in a fluid drachm of extract of taraxicum, every two hours, notwithstanding the fact that he had diarrhœa at the time. By the next morning the temperature had fallen to 100.1°, and by the following evening to 99°. I then gave the quiniæ sulph. less frequently from the fact that cinchonism was becoming evident, and I added to the treatment ten drop doses every three hours of dilute nitric acid. Next day the temperature and pulse were normal, and the coating of the tongue began loosening from the tip; and the patient's spirits were good, and he expressed a desire for food. From this period forward convalescence proceeded without interruption.

Karl L——, aged 4, was taken suddenly sick at 3 A.M., with symptoms of a chill, followed by high fever. At 5 A.M. I saw him, and found his pulse 124, his temperature, 104.3°; his tongue heavily coated, except at the edges and tip, which were red. There was no complaint of pain, nor any indications whatever of local inflammation. The case was clearly one of continuous malarial fever, such as I have repeatedly seen. I ordered the following:

℞ Quiniæ sulph.,
Pulv. acaciæ..... āā gr. xxx
Glycerinæ.....fʒij
Aquæ.....q. s. ad.fʒj
M. Sig.—A teaspoonful every three hours.

I also gave a few moderate doses of calomel, with a little extract of hyoscyamus, to move the bowels, which were reported to have been torpid for a few days. At 5 P.M. the pulse had fallen to 102, and the temperature to 103.5°. The quinine mixture was continued, as there were no evidences of cinchonism. Milk was regularly administered. The next morning the pulse was again 122, and the temperature 104.1°. The same treatment was continued during the three succeeding days, the case remaining in the condition as already described. With this dosage of 30 grains of quinine every twenty-four hours, there was only moderate

cinchonism, the child showing only occasional deafness and passing delirium. On the morning of the sixth day the pulse had descended to 90 per minute, and the temperature to 100.5°. The coating on the tongue began to flake and disappear, and the child's expression to brighten. On the seventh day the pulse was 80, and the temperature 99°. On the eighth day convalescence began, and continued without an interruption. During all this time the skin showed no signs of moisture. The bowels had, also, to be moved by remedies.

This continuous type of malarial fever appears to present itself most frequently in children, although I have had a goodly number of cases among adults. In every instance there seems a tolerance for quinine, and the dosage necessary to produce physiological effects is out of proportion to the age of the patient.

Towards the close of these cases, a little carbonate of ammonia is often useful. In adults, I often supplement the quinine treatment with dilute nitric acid.

I have treated these same forms with prepared lemon-juice, and have had uniformly good results. I think, however, that with children, while it is a more pleasant remedy than the quinine mixture, it tends more to disturb the stomach. Owing to the amenability of those continuous forms of malarial fever to quinine, I have tried the second remedy less frequently in them than in the irregular varieties.

These cases show that the prevalent belief that malarial poison is confined to low, marshy regions is ungrounded. They also demonstrate that each section of country has its indigenous types, and to be successful the practitioner must treat what is before him irrespective of any preconceived notions.

—The Medico-Legal Society of New York offers prizes of one hundred, seventy-five and fifty dollars respectively for the best, second best and third best essay on any subject within the domain of medical jurisprudence or forensic medicine. Competition will be limited to active, honorary and corresponding members of the Society at the time the award is made, but is practically open to all students of forensic medicine, as all competitors may apply for membership in the Society, which now has active members in most of the American States, in Canada and in many foreign countries. For further information regarding the competition, apply to the Secretary of the Society, Albert Bach, 140 Nassau street, New York.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of December 8, 1887.

Dr. B. F. Baer presented the specimen and read the following report of

A Case of Traumatic Hemorrhage into an Ovarian Cyst; Operation; Recovery.

I feel warranted in presenting the specimen and relating the history of this case because of its unusual character. E. D., 45 years old, married, the mother of seven children, youngest being seven years old. She had a miscarriage two years ago. She had always, until the present trouble, enjoyed good health. In December, 1886, while engaged in re-arranging her furniture, she lifted one end of a heavy chest. She soon after became conscious of a slight pain in the left ovarian region; but she continued with her usual work. That night, however, she was awakened by a sharp pain in this region, so severe as to cause her to "bend and writhe in agony." The pain extended down the left thigh and to the back, was accompanied with nausea and vomiting, and continued with great severity during the entire night before she obtained any relief whatever. On the next day her entire abdomen had become very tender and swollen (tympanitic), but the severe pain of the night before had subsided. She gradually recovered from this attack, and was about again within two weeks; but she still had occasional attacks of sharp pain, and was treated for neuralgia. Soon after this she noticed that her abdomen was larger than usual. She had changed physicians, and was treated for "dropsy and worms" by free purgation. This greatly prostrated her, and caused a return of the pain and other symptoms of the first attack.

My friend, Dr. O. K. Adams, was now called, and found the patient in great agony, the pain being most severe in the left ovarian region, but extending over the entire abdomen, which was tympanitic. The thighs were flexed and her expression anxious. The temperature was 103°; on the next day it had risen to 104°. She remained very ill through the next few weeks, after which she gradually improved. When the tympanites and tenderness had subsided enough to permit an examination, Dr. Adams discovered a cystic tumor in the lower abdomen, which he correctly pronounced ovarian. As soon

as she was able to be moved, the patient was sent to me.

An examination, with the patient in the dorsal position, discovered the abdomen to be distended by a circumscribed projecting mass, which occupied a position between the umbilicus and the pubis, and was about the size of the pregnant uterus of the sixth month. It extended more to the left of the median line than to the right. There was resonance over the entire surface of the abdomen, even over the tumor on light percussion; deep percussion, however, gave a dull note. By palpation, the tumor was found to be fixed to the abdominal walls and deeply in the left pelvic region. Vaginal examination showed the uterus to be retroverted, and upon it the lower surface of the abdominal tumor. Toward the left of the uterus a nodular mass was felt, apparently connected with the lower surface of the tumor. Movement of the tumor caused the uterus to move with it. Fluctuation was elicited by bimanual palpation. I advised immediate removal of the tumor, although the patient had not yet fully recovered from the last attack of peritonitis. The temperature was still above 100°, and was sometimes 101° in the afternoon. This advice was based upon the recurrent character of the inflammation and its probable traumatic origin, such as twisting of a pedicle or rupture of a blood-vessel. Rupture of an extra-uterine gestation sac had been suspected, although signs of pregnancy had been absent. There had not been suppression of menstruation, but, since her first attack of pain, her catamenia had been very profuse, lasting from ten days to two weeks.

The operation was undertaken on March 15, 1887. An incision was made three inches in length in the usual position, and the tumor exposed. It was now found that adhesion between the cyst wall and that of the abdomen was so intimate as to make it difficult to distinguish which was the cyst and which the peritoneum. I began by separating the tumor from the peritoneal surface, hoping to find a place where adhesion did not exist; but in this I was disappointed, for the peritoneum was firmly glued to the anterior and lateral surfaces of the cyst wall, while above the intestines and omentum were closely adherent to it. The tumor was now tapped, and a thin serous-looking fluid tinged with blood was drained away. The cyst was only partially emptied, as it contained a semi-solid material which could not flow through the canula. Room had, however, been gained so that the dissection could be continued. By a careful manipulation the upper part was separated from the intestines and omentum by amputating the latter, when it was found that the lower lateral surface was adherent to the sigmoid flexure, while the base of the tumor, broad ligament and uterus were so united as to form one mass. After further dissection the cyst was drawn out, and the short, thick pedicle examined. This was found to contain masses of thick, clotted blood, both within and around it. After further cleansing and examining, this nodular mass was found to be the Fallopian tube distended at several points with clotted blood. A temporary ligature was now thrown around the base of the cyst, which was then removed. This facilitated the further dissection which was necessary to form a proper pedicle. The latter was then transfixed and tied, and the smaller mass cut away. The right ovary was healthy, and was not removed. The abdominal cavity was next thoroughly cleansed, a drainage tube inserted, and the incision closed. The patient recovered and went home on the twenty-eight day after the operation, but it cannot be said of her that she recovered "without a bad symptom." She did comparatively well during the first four days, but on the fifth day her temperature rose to 103°, although there was no pain or other symptoms of active inflammation. On the next day it was 104°. The patient now complained of pain at the seat of the pedicle, and the left leg was found to be slightly swollen. The drainage tube was now removed, although there was still some discharge through it. The bowels were moved by a turpentine enema. Her improvement after this was slow but sure, and she sat up on the eighteenth day.

Examination of the specimen, after its removal, showed it to be a thin-walled monocyst. It was quite half-filled with a fibrinous material. This was not attached to the cyst wall, and resembled coagulated blood in process of organization. The lining membrane of the cyst was smooth, except at several places where a dilated vein as large as a quill was to be seen. The knotted, irregular mass which formed the pedicle was the Fallopian tube and broad ligament. Why it was in this condition is difficult to determine, unless it was from twisting of the pedicle; but this could not be fully made out at the operation. The dilated condition of the veins in the cyst and in the pedicle, and the evidence of hemorrhage within the cyst cavity as well as around the pedicle, render it probable that rup-

ture of blood vessels from stasis had taken place.

Dr. B. F. Baer also presented the specimen, and read the report of

A Case of So-called Ovarian Abscess.

This occurred in a girl of 17 years of age, who was sent to him on Nov. 1, 1887. Puberty was established at eleven years of age, or rather she began to loose blood from the womb at that time, for she has never normally menstruated. As a rule, there would be a metrorrhagia every ten days to two weeks, sometimes lasting a whole week, but usually only three or four days. No serious trouble attended this flow except that she sometimes felt worn out, although it was not at any time excessive. At first, after puberty, the intervals were longer, but gradually decreased until she was almost constantly flowing. She had never suffered much until last August, when she was taken suddenly with pain in the left ovarian region. The pain was sharp, cramp-like in character, and came on during the day; but she was not aware of any cause for it, such as over-exertion. The attack occurred a day or two after the cessation of one of these attacks of metrorrhagia. The pain increased in severity until it compelled her to go to bed, where she remained a week in great suffering under the care of her physician. She continued in bed four or five days after the pain ceased, as the result of prostration and under advice. After this there was an interval of thirty days before the flow returned, the longest interval she had ever had. Then she began flowing again, October 2, and continued to flow regularly every day for the next thirty days, at which time she first consulted me. Examination revealed the vagina rather patulous, cervix soft and uterus occupying a position behind the symphysis pubis, where it was held by a tumor which occupied Douglas's pouch. The tumor extended as high as the superior straight, and seemed about the size of a fœtal head. It was rather elastic, apparently circumscribed and fluctuating. I prescribed gallic acid for the metrorrhagia and advised rest. At the next visit I gave the patient ether and determined that the tumor was almost certainly of a cystic character, and probably adherent to the posterior wall of the uterus, and to the pelvic tissues generally. I advised its immediate removal, because of the grave symptoms which it had no doubt produced, and because of the fear of its rupture and possibly fatal injury to the patient.

She entered my private hospital on November 22, and was operated on November 24. An incision two inches in length was made in the usual position, and two fingers introduced into the peritoneal cavity. I found the omentum adherent to the posterior wall of the uterus and upper surface of the tumor. This I dissected off, and found a tumor the size of a large orange, slightly flattened, occupying a position behind the uterus extending to the left. It was adherent everywhere, and seemed at first to be subperitoneal, but was soon discovered, after some adhesions were separated, to be intraperitoneal. The adhesions were quite firm, and it took ten minutes of careful manipulation to entirely release the tumor, which was then brought up to the opening in the abdomen by placing two fingers under it. It was next punctured with a trocar and canula, and drained of about six ounces of thick laudable pus. It was thus made small enough to readily pass through the incision. The tumor was of the left ovary. The pedicle was very small and short, consisting of the ovarian mesentery and ligament. I could readily have removed it without removing the tube, so free was it from adhesions to that organ. Indeed, the tube seemed to be entirely free from disease. The opposite ovary and tube were perfectly healthy, and were not removed. There was some hemorrhage, but it ceased after a little sponging, and the abdominal incision was closed, drainage being considered unnecessary. The patient complained of great pain after recovery from the anæsthetic, and it required three hypodermics of morphine to relieve her. There was also violent reaction. Four hours after the operation the temperature was 102°, and the pulse 148. This violent reaction was no doubt emotional, for as soon as the patient became quiet the temperature and pulse returned to the normal, and did not again show the slightest indication of trouble. Her recovery was remarkably rapid and uneventful. She sat up on the eleventh and went home on the seventeenth day after operation.

Examination of the specimen shows it to be polycystic, the larger cyst-cavity, which contained the pus, having a peculiar reddish granular-looking lining membrane. At places papillary tufts are to be seen. The smaller cysts contained a clear fluid and have a smooth lining membrane. This case is interesting because of the early age of the patient, the early puberty, the frequent recurrence of the metrorrhagia and the purulent character of the fluid contained in the cyst,

the latter condition constituting what is commonly called ovarian abscess. The term is a misnomer. True ovarian abscess probably never occurs; that is, an inflammation in cellular tissue or stroma of the ovary which results in "a collection of pus surrounded by a wall of lymph"—the surgical definition of abscess. When a pus cavity is formed in an ovary, I believe its origin can always be traced to a previously existing cystic degeneration of the ovary, the purulent formation being secondary.

Dr. J. Price remarked that tubal disease may exist in virgins, the probable cause of infection being unclean hands and instruments of an examining physician. The small drainage tubes were introduced in London by Dr. Bantock, and were of seven different lengths. A dangerous rise of temperature certainly did at times arise in some cases from emotional causes, a good example of which he thought had occurred in New York at the Woman's Hospital. A patient was operated on in one of the cottages and was doing nicely. During convalescence she was moved into the hospital much against her wish; her temperature rose immediately and she died in a few hours.

Dr. Hirst said that "emotional fever" was often observed after laparotomy. He had seen the temperature rise above 100° in an instant because he had told the nurse in the hearing of the patient that the stitches were to be removed the next day. He had seen some very extraordinary cases of emotional fever in the puerperal state, having more than once seen the temperature rise suddenly to 104° in consequence of a fit of weeping. This phenomenon was not very uncommon in the Maternity Hospital where the patients are for the most part young unmarried primiparæ.

Dr. Kelly observed that instrumental infection of a healthy woman is a very real danger to which many victims have been sacrificed. He advises aspiration in all small cystic tumors before proceeding to their delivery at the incision; in this way a certain proportion of lives will be saved by avoiding the frequently inevitable rupture with an escape of poisonous contents amongst the intestines. A systematic use of the drainage-tube is advisable, but not such tubes as are in common use. His friend, Dr. Dudley, of Chicago, uses a very delicate little tube which can be slipped in between the sutures and answers all purposes, especially when used as Dr. Kelly has long done, by leaving in a piece of twisted absorbing cotton, which carries everything up from the bottom of the tube by constant capillary attraction.

Dr. Longaker believed that many cases of diseased tubes were due to filthy instruments and careless manipulation. A case had come under his care, an unmarried woman, of undoubted virtue, suffering from bilateral disease of the appendages. Her history was that of dysmenorrhœa, for which the os had been incised. After this operation she was confined to bed for six months. Some months later she came into his hands, and was also seen in consultation by the late Albert H. Smith, who agreed in the diagnosis. The case passed out of his hands without operation. The conclusion that the operation was not done under perfect conditions is forced upon us, and also that by reason of this carelessness her condition was rendered worse than it had been.

Dr. Drysdale, in reply to a question from Dr. Baer, said that often when the ovarian cells are crowded together the fluid will have the appearance of pus. The application of acetic acid will, however, always differentiate them from pus cells. Pus and ovarian cells could exist in the same fluid, but in cases where the pus cells became in excess the ovarian gradually disappeared. A blow on the abdomen over the ovary has caused an inflammatory process which resulted in an ovarian abscess. Dr. W. L. Atlee had always drained after serious operations, but in his day tubes had not been introduced; he had used tents.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Semi-Annual Conversational Meeting.

The President, F. P. Henry, M.D., in the chair.

Abstract of the address delivered by W. T. Councilman, M.D., on

Some Further Investigations upon the Malarial Germ of Laveran.

This organism, first described by Laveran, has been met with in every case of malarial fever which the writer has encountered. The organism is in high degree polymorphous, and ten tolerably distinct forms may be found in the blood. Some of these evidently represent different stages of development, and the connection between them is obvious. Others present such marked differences in form that no connection between them can be made out. Some of the forms are only found outside of the red corpuscles, and others are found free in the blood. The forms described

are: 1, non-pigmented, small amœba-like bodies inside the red corpuscles; 2, pigmented bodies larger than No. 1, also in red corpuscles; 3, pigmented bodies about the size of red corpuscles; 4, segmenting forms of the No. 3 body; 5, small hyaline bodies, which are formed by this segmentation; 6, a crescent-shaped body, with pigment in the centre, the horns of the crescent being often connected by a fine line; 7, round or oval bodies, which differ from No. 6 in shape only; 8, a pigmented body provided with numerous, long, actively-moving flagellæ; 9, actively-moving, free flagellæ, which are evidently derived from No. 8; 10, a pigmented body with an active, undulatory movement of its periphery. The first five forms are found only in intermittent fever, No. 4 only being seen in the blood during the chill period, and its presence is invariably connected with the chill. Nos. 6 and 7 are found in cases of malarial cachexia. The most interesting forms, and about whose parasitic nature there can be no doubt, are the bodies Nos. 8 and 9. These are generally absent in blood taken from the finger, but they may be found in any type of the disease. They are the only forms of the organism whose presence in the blood is not associated with a special type of the disease. They were found, however, in fifteen out of the twenty cases in which the blood of the spleen was examined. Of these twenty cases, twelve cases were of malarial cachexia, and eight of intermittent fever. In the twelve, they were found ten times, and in the eight cases of intermittent five times. From this it seems probable that Laveran was right in considering the flagellate organism the most important form of the parasite. The influence of quinine on the intra-corpuscular forms of the parasite is most marked. Doses of fifteen grs. t. i. d. for two days in succession were found sufficient to cause them to disappear. The effects of the quinine were not so apparent in the other forms. The crescents were apparently not diminished in number in one individual after he had taken forty-five grains of quinine daily for seven days, and sixty grains daily for four days.

Dr. Wm. Osler said the thought which had struck him most forcibly in looking over this subject was the almost perfect unanimity which has prevailed among the different observers as to the appearance of these organisms. With the sole exception of the segmented form (No. 4), Laveran and the early observers had described them all. His own observations, since the communication he had presented to the society last year, had been somewhat limited. He had, however, made a series of observations upon the blood of fishes and birds, since it has been stated that bodies resembling Nos. 1, 2 and 3 had been found in the blood of carp and some water-fowl. Prof. Baird had offered him facilities for this work at Wood's Hole, and had kindly furnished him with forty-five carp. He had failed to detect any such organisms in the blood of these. In the blood of a goose sent him from Ontario, he had found one or two pigmented bodies. It had been stated by Dr. McCallum, who sent him the goose, that the bird had malaria. However, the bodies were not numerous, nor was the temperature of the goose elevated, nor, as far as he could make out, had it chills. Dr. Councilman had not figured one body, which is very peculiar indeed, namely, a solid body in the centre of a clear space. It stains like a micro-organism, varies in size, and although the body itself does not change in form, yet there are sometimes changes in outline in the clear space surrounding it; they were somewhat abundant in one case only. One other point with regard to the clear bodies (No. 1), in five or six instances he had seen such bodies pass out from the corpuscle, remaining out and undergoing no further change of form. He was not altogether prepared to say what was the relationship of these bodies to the other bodies described. It has been claimed that similar changes can be obtained by special methods of staining the blood. The most important question is, first, to determine the relationship of the hyaline to the pigmented bodies, and the possibility that the hyaline may not be directly associated with them. He was convinced that the pigmented and segmented bodies were merely different stages. He could fully confirm what Dr. Councilman said with regard to the crescents. They are most peculiar and interesting bodies, occurring in the chronic cases and in those in which there had been no chills. Three weeks ago he had lectured on a case as one of mild typhoid fever; it had lasted eight or ten days with constant fever—up in the evening, down in the morning; slight enlargement of the spleen; no spots. His resident physician examined the blood and found what he thought were crescents. The case got rapidly better, left the hospital, and returned in a few days with a distinct chill, with crescents in the blood and a well marked remittent fever. The motile forms he had not seen nearly so frequently as Dr. Councilman; though he had not examined the blood from the spleen, they had been present in eight or ten cases. Nor had he seen free filaments nearly so often; when h

e

wrote his paper he had not seen them at all. Since then he had watched the process of separation. It was out of the question to suppose that the crescents or motile forms could come from degenerations in the stroma of the corpuscle, but that the hyaline forms resulted from such changes was not altogether improbable. Further investigations were necessary to determine this point.

Dr. J. P. C. Griffith called attention to the diagnostic value of these organisms, and instanced a case when, from the indefinite history and symptoms, he was unable to make a diagnosis until after an examination of the blood, when a short course of treatment resulted in a cure.

Dr. H. C. Wood said that no one seemed to have made any connection between the crescents and the amœboid forms; they seem to differ in that these are destroyed by quinine, those are not affected. We know that malarial cachexia is cured by quinine, arsenic and iron; if these remedies have no effect on the crescents, what connection have these bodies with malaria? and what becomes of them? Do they eventually disappear?

Dr. Formad asked whether these organisms are the same as those bodies described by Hütter some twenty years ago.

Dr. Councilman said, in concluding the discussion, that Hütter described moving bodies attacking the red corpuscles, existing in all forms, and apparently almost everywhere else. These observations had never been confirmed. The point raised by Dr. Wood had always puzzled him, and for a long time he had tried to reconcile himself to a belief in two distinct diseases; but this he could not do, for always as the other forms disappear the crescents appear. He had never seen the crescents unless with a history of previous chills. He was not altogether prepared to say that quinine had no effect on the crescents, though in several cases he had given it in large doses with no results. Still, in some cases they do seem to disappear. He thought, with Dr. Osler, that the crescents could not be possibly produced by changes in the stroma of the corpuscles, though some of the other forms might.

W. E. Hughes, M.D., Recorder.

—Small-pox, which first made its appearance in Catasauqua, Pa., several weeks ago, continues to find new victims, through the carelessness of persons who visit the patients and men who convey patients to the Lehigh county pest-house. There are cases now in Slatington and White Hill. Three new cases have developed at Catasauqua.

Reports of Clinics.

PENNSYLVANIA HOSPITAL.

MEDICAL CLINIC—PROF. DA COSTA.

Acute Pericarditis attacking a Heart with an already Diseased Mitral Valve.

This patient, a lad of 17, came to the hospital with a well-marked attack of pericarditis; but, in addition to the friction-sound and other signs of this disease, a soft, somewhat muffled systolic murmur was heard at the apex of the heart. The previous history of the case showed this valvular lesion to be one of long standing. Under treatment, the acute inflammation of the pericardium passed away, and with it the frictional rub, pain, tenderness, etc. As these gradually disappeared, the old mitral murmur reasserted itself, and was heard much more distinctly. The pericardial disturbance yielded to acetate of potash, one-half ounce being given in the twenty-four hours. The pain and restlessness were allayed with small doses of opiates. At the same time, in view of the patient's somewhat anæmic condition, ten drop doses of the tincture of the chloride of iron were given thrice daily. As the disease advanced to a favorable termination, blisters were applied over the cardiac region, followed by poultices, and the potash was gradually reduced.

Now, however, that the inflammation of the enveloping membrane of the heart has been conquered, we find that the heart itself, as a result of its old mitral disease, is in a state of dilated hypertrophy. The area of cardiac dulness is much increased, and the impulse of the heart is very perceptible. What line of treatment shall be continued here in order to keep this pathological change within bounds? Without wishing to depress the patient, something must be given to control the progress of the hypertrophic process. Five drops of the tincture of veratrum viride were ordered to be taken each evening, and the iron was continued in sufficient doses to gradually enrich the blood.

Acute Articular Rheumatism; Yearly Recurrence; the Salicylates vs. the Potash Salts.

The patient, a young man 26 years old, was admitted to the hospital December 18, 1887. His father had had heart disease, but died of some renal disorder. His mother is living and healthy. The man's personal history is most remarkable. He has never been afflicted by any other disease than rheuma-

tism, but this has pursued him relentlessly. His first attack of it, the acute articular form, occurred when he was but eleven years old, and every year without exception since then, either in the late fall or early winter, he has suffered from a return of the disease, each time with all its attendant distressing symptoms fully developed. For a number of years past he has also experienced severe dyspnœa, and much cardiac pain and palpitation. His present illness began about Dec. 12, and when he was admitted to the hospital on the 18th, his temperature was 102°; his wrists, shoulders and knees were swollen and tender; there were general pains throughout the body; and, in addition, there were considerable dyspnœa and cardiac pain. The heart's action was diffused and forcible; apex-beat found in sixth interspace, one inch to outer side of the nipple-line. Its area of dulness was increased. Soft murmurs were heard over the mitral and aortic valves.

The treatment adopted at the outset consisted in the administration of salicylate of sodium in ten grain doses every second hour until nine doses had been taken, when it was continued at longer intervals. During the ensuing two or three days the pains were lessened and the patient made more comfortable, but the decline in temperature was very slight. On the 21st it began rising again, and, though the pain and discomfort were not noticeably increased, it went up steadily until, on the 25th, it was 103°. A day later a marked to and fro friction-sound was heard, with its point of greatest intensity over the left ventricle; and, on the same day, signs of pleurisy were discovered at the base of the right lung.

Here, then, was an active development of rheumatic inflammation of these two serous membranes, the pericardium and pleura, in spite of the fact that the patient had been under the influence of the salicylate salt for several days. Acetate of potash, one ounce in the twenty-four hours, was now substituted for the salicylate of sodium; and, the pulse being a trifle weak, two ounces of whiskey were ordered during the day. Moderate doses of quinine were also added to the treatment; poultices were applied over the cardiac area; and, at night, morphia, grain $\frac{1}{6}$, and atropia, grain $\frac{1}{120}$, were given hypodermatically to secure rest. Under this treatment, with occasional blisters over the heart, the patient's symptoms underwent a rapid change for the better, and he is now fully convalescent. In the intervals between his yearly attacks of this disease, the patient had suffered more or less constantly from general rheumatic pains; he is easily affected by changes in the weather, and has to exercise great care in protecting himself against them. To modify as far as possible these manifestations of an established chronic condition, the iodide of potash will now take the place of the acetate, and will be continued for some time.

Remarks.—The lecturer considered this case particularly valuable on account of the very forcible way in which it demonstrated the utter inefficiency of the salicylates to limit the inflammatory element of this disease to the articulations. Not only do they fail to *prevent* the involvement in this process of the other serous membranes, such as those which were attacked in this case, but they exercise no influence whatever over these complicating lesions when they happen to be already developed. In both these respects he holds that the alkaline treatment with the potash salts is of infinite superiority to that by the salicylates.

He also called attention to the use of stimulants in cases of this kind, when evidences of heart failure become apparent. He gives them at such times unhesitatingly. He allows no theoretical considerations of the malevolent influence of stimulants on the inflammatory process to interfere with their administration. His first care is to steady and sustain the heart, knowing that, this being accomplished, powerful assistance will be afforded those other remedies which are acting on the existing disease, obstructing its progress and gradually eliminating it. His preference is for alcohol. Digitalis is of use in combination; but, if occasion should arise when he would have to choose between the two, he would select alcohol as being of more general applicability and of more satisfactory action. His advocacy of this system of stimulation is founded on long experience of its value, on the fact that his cases recover when so treated with much greater certainty than when it is omitted.

BELLEVUE HOSPITAL, NEW YORK.

NEUROLOGICAL CLINIC—PROF. JANEWAY.

Pott's Disease.

Professor Janeway opened his clinic on December 20, 1887, with a case of Pott's Disease, in its early stage. This patient, a man, forty years old, had spitting of blood two years ago, which recurred but once since, and that a few evenings after that date. He now presents some râles in the upper part of the left lung. Last summer he was

taken with a pain in the back upon lifting a barrel, which pain has since become persistent, and is accompanied with a certain amount of distress, slight difficulty in evacuating the bowels, and slight fever now and then. At present a jarring pain in his side, with a band-like feeling across the lower part of his chest, are superadded to the above symptoms, which have become somewhat aggravated. The examination revealed a slight impairment of the tonicity of the abdominal muscles, and a small numb-zone, corresponding to the eighth dorsal nerve upon the left side, in front; but no abnormality of the spinal column was observable. In picking up an object he does so gingerly. Jumping, or downward pressure exerted upon the spinal column, causes pain in the back. Relief is obtained on being raised from the axillæ.

Warning the students to be careful in arriving at a conclusion, Prof. Janeway cautioned them also to look with suspicion upon such symptoms as *persistent* lumbago, with slight fever. "It is in lumbago that one has also to bear in mind the probability of the existence of an aneurism or of gravel." In illustration of this point, he mentioned the case of a man who brought successful suit against the city for $25,000 damages, for injuries sustained by a fall. In this case the three expert neurologists, although agreeing that there was an affection of the spinal cord, were nevertheless of a different opinion as to the nature of that affection. One pronounced it a lateral spinal sclerosis, another a multiple spinal sclerosis, and the third an antero-lateral sclerosis. This patient called on Dr. Janeway some time thereafter for treatment, and was referred to Dr. Sayre as a pronounced case of Pott's disease. As regards treatment in the present case, Prof. Janeway proposed trying the plaster-jacket.

Aphasia.

Another patient was then presented to the class, who was a right-handed man of about fifty years of age, and represented a case of "ataxic aphasia with amnesic agraphia," the disease not being complicated with paralysis either of the face or of the extremities. He understands what is said to him, yet is unable to speak; and, though he recognizes the various objects held before him, he can only mimic their uses. When told to get a piece of chalk behind a certain box on this or that table, or to bring the book the doctor has in his hand, he seeks the one or takes the other and returns with the articles named. When requested to write his name, he does so, and correctly. He is also able to *copy* writing, but is not able to read what he has copied—not even his name when just written. When a knife is shown him, he recognizes it, which is manifest by his gesticulations; and he endeavors to speak his name, but, being unable so to do, he becomes greatly distressed. When told to write it, he hurries to the black-board, as if fearful of forgetting its name, begins the first letter or letters correctly, perhaps, becomes puzzled, then substituting one letter for the proper one, or one similar in sound or form, now erasing one and adding another, and finally either finishes the word incorrectly, or fails altogether to finish it. Smell and taste, as tested, were preserved. After much difficulty the following fact was elicited, namely, that he fell from a ladder, striking the back part of his head.

Professor Janeway thinks that the hemorrhage due to *contre-coup*, which had taken place in the tempero-sphenoidal lobe, gradually extended to the region of the lower frontal convolution, and thus caused the symptoms which are present in this case.

Syphilitic Endo-arteritis.

The patient, twenty-eight years old, presented syphilitic scars in various regions of the body and extremities. His solar reflex is preserved. He has paresis, with slight rigidity of the right leg, and a complete paralysis of the arm of the same side. The pupils are contracted alike, and there is oscillation of the pupils. The tongue is only partially protruded. The mental condition of this patient was so much impaired that it was impossible to obtain a complete history. This condition, however, was ascertained to have come on within the last ten days, and more or less gradually.

COLLEGE OF PHYSICIANS AND SURGEONS.

CLINIC FOR DISEASES OF CHILDREN—PROF. JACOBI.

Cyanosis.

At this clinic, held on January 4, 1888, Prof. Jacobi brought before the class a pale, ill-nourished child, two years and three months old, which had been afflicted with loose bowels immediately after its birth, and now presented a bluish appearance, especially of the legs and hands. Upon the mother remarking that the child never smiles, Prof. Jacobi remarked that the absence of a smile was pathognomonic of various conditions.

"A child in pain will not smile; a child ill of some disease not complicated with pain will not smile; but the smile is notably absent in those cases depending upon innutrition of the brain. This child was bluish since birth. The question is, whether this bluish appearance is temporary or permanent. Cyanosis also occurs in adults. When once established, it may become permanent or appear only under certain conditions. The distress of the patient is at times increased, and he is liable to paroxysms of dyspnœa and palpitation. Cyanosis is not due to the admixture of venous and arterial blood, but to an obstruction to the circulation. In the development of the heart in the embryo, a partition gradually arises from the lower part of the right wall, and ultimately separates the ventricular cavities. The septum auriculorum, formed about the same time but not completed during fœtal life, leaves an opening, which is the foramen ovale. The blood entering the right auricle by both the superior and inferior venæ cavæ, now takes the following course: that from the superior vena cava enters the right ventricle through the tricuspid valve; that from the inferior vena cava, after passing into the left auricle through the foramen ovale, enters the left ventricle. The blood from the left ventricle is then propelled into the ascending aorta, and that from the right ventricle into two paths—by the one, to the lungs through the pulmonary artery, and by the other into the descending aorta through the ductus arteriosus. The closure of the foramen ovale, as well as the contraction of the ductus arteriosus, takes place some days after birth. If the foramen ovale is *not* closed immediately after birth, it is said to result in cyanosis. This is *not* so. Any book giving you this information will not be recommended by me.

"This child presents a systolic murmur which cannot come from a mitral valve, but from the aorta, because the murmur has much too great an area and is heard at too great a distance. Again, a congenital heart disease is as a rule upon the right side, and acquired upon the left.

"Can we benefit the baby? Most babies die at two months, but a few live to the age of six or seven years. We can hold out no hope, and we have no remedy. We expect them to die. All we can do is to give a little digitalis to relieve the breathing, Mellin's food for the imperfect digestion, and narcotics, which are necessary, for the sleeplessness. Of the latter, opium in doses of one-twentieth of a grain at night, or, if this is not sufficient, then a single dose of a one-sixteenth, or a one-twelfth, or even one-tenth of a grain; paraldehyde in a half a teaspoonful dose, at night, dissolved in alcohol and taken in some syrup, is better than the former, as it causes no headache; amylen hydrate in an eight to ten grain dose—these three are the best."

Heart Disease and Gastric Ulcer.

This patient was a girl, fifteen years old, who had been attacked with measles at two years of age, and with scarlatina and rheumatism in her ninth year. One year ago she had dyspnœa and spitting (?) of blood, which has always been of a reddish color, and, for the last month, pain. "As we hear, this patient has had rheumatism. Children attacked with rheumatism do not as a rule take to bed. Such attacks are supposed by the parents to be caused by growth—the so-called 'growing pains.' The endo-carditis complicating this affection is present, in children, from the beginning." The examination of the lungs revealed nothing abnormal. "The child presents a systolic murmur, which murmur would be transmitted through the carotid if the seat of the trouble were in the aorta; not being so transmitted, there must be a lesion at the mitral valve, and this lesion an incompetency. Moreover, she bleeds. This bleeding may either come from the stomach or from the lungs. It is therefore important to note the color of the blood. As blood is acted upon by the various fluids of the body, as for example, in a hemorrhage occurring in the alimentary canal, it is necessarily changed in character. That coming from the stomach would be of a rusty or coffee-ground tint; that from the duodenum—escaping from the bowel—of a tarry color; whilst that from the lungs would be red. The characters, however, vary also with the amount and rapidity with which it has escaped. Hemorrhage is the result of some disease or congestive condition, induced by obstructions in the circulation. Congestion, if extensive, may give rise to a rupture, or a thrombus may form in a distant part. When such thrombosis takes place, you have gangrene or ulcerations following. The round ulcer of the stomach is of that character—that is, due to a thrombus. So it is here, this patient has a gastric hemorrhage from a mitral disease. That a hemorrhage may take place more readily in some persons than in others is due to the feebler structure of the blood-vessels—the most feeble more readily giving way. Thus it is that a blow or fall may give rise to an aneurism. A healthy artery ruptures less readily.

"As regards treatment, choice can be made of digitalis, strophanthus, or spartein. Caffein ought not to be given, since it causes congestion. Then, again, remedies having an influence upon connective tissue may be given, as arsenic and phosphorus. It must, however, be remembered that agents causing a reconstruction of the connective tissue in small doses cause destruction in large doses. I should give two drops of Fowler's solution in half a tumblerful of water, three times a day, and subsequently increase the dose to three drops."

Hospital Notes.

University Hospital.

Service of M. Howard Fussell, M.D., Assistant Physician to the Medical Dispensary of the University Hospital.

Tobacco Heart.

Of the cases of heart disease recently treated in the writer's room, at the dispensary, nine were diagnosticated as functional disorders due to the excessive use of tobacco. All the nine cases occurred in young men between the ages of seventeen and twenty-seven years.

The tobacco was used in all the cases in the form of chewing, the amount ranging from a half a pound to one pound a week. The habit of chewing was begun early in life in all the cases; in one case at the age of five years; the oldest age noted at which chewing was begun was twelve years; the average was seven years.

The symptoms complained of were palpitation, pain and dyspnœa. Palpitation was present in all the nine cases, and was greatest upon making any exertion. Irregular action of the heart at the time of the examination was noted in only one case. Pain was complained of in seven cases, and always had its seat immediately over the heart or under the sternum. Dyspnœa was complained of in only three cases, and was not excessive. Hypertrophy of the heart as evidenced by increased area of cardiac dulness was noted in two instances. In both cases the dulness extended to the right edge of the sternum. In the two cases in which hypertrophy had occurred, care was taken to exclude any other cause than tobacco. No murmurs were noted in any of the nine cases.

Treatment consisted in prescribing total abstinence from the use of tobacco, and in some cases, where this alone did not suffice, the moderate use of bromide of potassium. Notwithstanding the great length of time during which tobacco had been used, and the early age at which the use had been commenced, this simple common-sense treatment usually sufficed to give entire relief after three or four weeks. In only one case was digitalis used.

Periscope.

An Exceptional Case of Aphasia.

Sir George E. Paget, Regius Professor of Physic in the University of Cambridge, reports the following interesting case in the *Brit. Med. Journal*, Dec. 10, 1887: The patient was a clergyman of studious, temperate and somewhat sedentary habits, and of the highest intellectual powers, with singular gifts of speech, preaching, and lecturing extempore, with rapid delivery, never hesitating for a word, and yet never wanting in exactness. He worked unsparingly, writing much. His temporal arteries were prominent and tortuous. He was sixty-four years old at the time of his first seizure. He was found shortly before 8 A.M., sitting on the side of his bed, rubbing his right leg, conscious but quite speechless. After an hour he had recovered the power of saying "yes" and "no," but no other words. His right hand and arm were paretic and ataxic. After nine hours the ataxy was less marked, and he could manage to speak a short sentence. Next day his power of speech seemed quite restored, and there were scarcely any traces of the paresis or ataxy.

After this attack, he abstained for a time from work; but, on returning to it, was not so perfectly fluent in preaching as formerly. A second seizure occurred nearly two a half years after the first. This, like the first, occurred before 8 A.M., soon after his leaving bed, and before he was dressed. He was heard to fall in his dressing-room, and his wife, going to him instantly, found him unconscious and muttering; but in a few moments he completely recovered consciousness and speech. When I saw him half an hour later I found paresis, ataxia, and impaired muscular sense in his left arm. He had not the slightest difficulty in expressing his thoughts, and inquired in a tone of surprise, "Where is my left arm?" It was out of his sight, being turned back under his head on the pillow. After seven hours the ataxia was no longer perceptible, and the next day he was convalescent. After this attack he reduced his work, gave up his church preferment and preaching, but continued his writing, chiefly by dictation, on

abstruse subjects, and with force and clearness.

Passing over events which have no immediate connection with aphasia, we come to his third and last seizure. This occurred nearly three years after the second. It was a violent attack of cerebral hemorrhage, occasioning complete paralysis and analgesia of the right side, almost entire loss of sight and hearing, consciousness being wholly suspended for some days, and afterwards very imperfect. He lived three years after this attack, but never again spoke an intelligible word, except on one occasion, "Do, do," when apparently becoming conscious of his inability to move his right leg. He sometimes talked—if it may be called talking—long and earnestly, with modulation of voice and expression of face as if he had conception of what he was uttering, but in the utterances was no articulate or intelligible word. Though sight and hearing were impaired, he preserved the sense of taste. After two months sensibility was restored in the right hand, and some power of movement.

He was kept alive by skilful and tender nursing, but the right arm became contracted, and two and a half years after the last seizure he nearly died of pneumonia (left). After this his strength and nutrition failed, bedsores formed, contracture came on in both legs, most marked in the right; respiration was often of the Cheyne-Stokes type, and six months after the pneumonia he died exhausted.

The point of special interest has yet to be mentioned. This gentleman was naturally left-handed. Yet, as the narrative shows, his aphasia accompanied right hemiplegia, and did not accompany the left hemiplegic attack. In this the case differs, I think, from any yet recorded. The general fact has been that aphasia has accompanied paralysis of the preferentially used hand, accompanying right hemiplegia generally, left hemiplegia rarely, and then only in the cases of left-handed persons. In the case related, the aphasia followed the ordinary rule of right-handed persons, though the patient was naturally left-handed.

The explanation of the anomaly may, I think, be found in the fact that, though left-handed for other actions, he wrote with his right hand, and was in the habit of writing much. It was not due to any association between speaking and gesticulation, for he had not the habit of gesticulating.

The case has a bearing on the debated question whether the ordinary location of the faculty of speech in the left cerebral hemisphere be due to congenital predominance of that hemisphere or results from the education of the right hand. For my own part, I believe that both these causes have their influence. But the case is an additional argument on the side of education, and it points to writing as the most potent of these educational influences. The ordinary rule of the organ of speech being in the same hemisphere that serves for the voluntary movements of the naturally predominant hand—this ordinary rule was reversed, and the reversal is the more remarkable because the congenitally predominant hand had remained the preferential hand for all actions except writing. The habit of writing much seems the only assignable cause for this reversal. And it may be held to be an adequate cause, for the memory of words will naturally go with the movements of the hand that writes them; and the process is simplified by using one and the same cerebral hemisphere for recollecting the words and for directing the hand in setting down their symbols.

It has been suggested, and with some reason, that it might be better for us—that we should be capable of more mental labor, with less fatigue—if we employed both hemispheres instead of throwing all the work on to one. The case I have related would not support this view, for the gentleman was capable of an enormous amount of mental labor. His only relaxation was chess.

The degree in which the education and employment of the right hand for writing operate in inducing the use of the left hemisphere for speech might be tested by inquiring more particularly into the circumstances of cases of aphasia with left hemiplegia in left-handed persons. Has this ever been noticed in persons much engaged in writing?

Fracture of the Coccyx and Passage of the Segment Per Anum.

Dr. W. J. Jolly, of Waldo, Fla., in a letter to the *Medical Record*, December 17, 1887, says that he was called to see a woman on November 1, 1887, who was a primipara, twenty-one years old, and in labor. Nothing unusual occurred until the head pressed against the coccyx, which did not yield. He then applied the forceps, and delivered the woman without any trouble or laceration of the perineum. Immediately after delivery she suffered intense pain in the region of the coccyx, for which she was given an opiate. An examination discovered some displacement of the coccyx, which he corrected, supposing the bone to be fractured. The opiate soon relieved the pain, and the patient

did not suffer any more until the ninth day, except that there was some tenderness in the region of the coccyx. She had some slight pain on the ninth day, and on the tenth she passed a bone per anum and sent it to him, stating that she thought she had passed a joint of her backbone. Upon examination he found it to be the lower segment of the coccyx. The woman had no trouble afterwards.

Contribution to the Ætiology of Affections of the Middle Ear in Childhood.

Dr. E. Pins says, in the *Jahrbuch für Kinderheilkunde*, that diseases of the middle ear are exceedingly common in childhood, and especially in the first few months of life. The exciting causes of these diseases are numerous, and most of them are well known; but, in addition to those which are described in the treatises on ear diseases, the author lays stress on the following: 1. The entrance of water into the external ear during the daily bath. 2. The difficulty of keeping the nose clean in children: the secretions are apt to remain in the nose, to decompose and to set up catarrhal and putrid inflammatory conditions of the nasal mucous membrane, which spread to the middle ear. 3. Catarrhal pneumonia is very frequently attended by middle ear disease, as is well known to be case with croupous pneumonia. As regards symptoms, the boring of the head on the pillow is dwelt on as one of special importance under the first heading. The three causes enumerated are dealt with in detail with reference to their differential diagnosis and treatment.—*Edinburgh Med. Journal*, Dec., 1887.

So-called Surgical Scarlet Fever.

This is the name given by many to any eruption resembling scarlet fever which comes on after a wound or operation, whether it begins at the injured spot or at a distance. Hoffa (Volkmann's *Sammlung*, No. 292), has analyzed a number of such cases to be found in various publications, and reduces them to four categories: The first three are not true scarlatina, but (1), a simple congestive vasomotor erythema, depending on a vasomotor reflex; (2), toxic erythema, caused by the absorption of secretion from wounds or other fibrinous ferments, or it may be brought on by the use of chloroform, carbolic acid, or corrosive snblimate; (3), septic erythema, sometimes very hard to diagnose from true scarlatina—after the rash fades there is occasionally desquamation; (4), a real scarlatina, arising in the usual way from infection. To deserve the name of surgical scarlatina, such cases must have become infected after the infliction of the wound or operation, and the exanthem must have commenced at the wound. Nine cases are selected from the literature of the subject. Hoffa is of opinion that a wound predisposes to scarlatina, as it presents a larger surface for the micro-organisms of scarlatina to attach themselves to, and in this way he explains the shortness of the period of incubation which has often been noticed.—*Edinburgh Medical Journal*, Dec., 1887.

Action of Antipyrin upon Nutrition.

At the meeting of the Academy of Medicine, of Paris, December 6, 1887, Albert Robin read a paper upon the action of antipyrin upon nutrition. As a result of his researches, he states that the quantity of urine is always diminished in healthy subjects, and in acute conditions it is diminished, but variably so. In chronic conditions the diminution is still the rule. The solid matters are diminished about 10 per cent. in the normal state, and in typhoid fever still more markedly. This diminution is much more striking in chronic conditions. In cases in which the disease compromises nutrition most, the diminution is most important. Urea and the urates are dimished, both in normal and pathological conditions; uric acid he found to be increased in health and variable in disease. The chlorides were diminished three times out of four. Antipyrin, therefore, diminishes the general disintegration, and particularly the disintegration of nitrogenous materials.

As to its therapeutic indications, since it exercises a depressing influence upon all nervous activity, its use is indicated to modify nervous excitability. This explains Germain Sée's happy use of it in the treatment of pain, in headache, migraine, neuralgias, in which it really exercises an inhibitory influence. But pain is not the only manifestation of nervous hyper-excitability; there are a number of morbid conditions in which it occurs, either as a preponderating or superadded element. It is in this way that antipyrin has been able to exert an influence upon certain painful affections of the heart, and to give even some success in certain cases of angina pectoris. As to the antipyretic virtues of antipyrin, the author is very distrustful; and he thinks it particularly contraindicated in typhoid fever, as it increases the slightly soluble waste products, while it diminishes the vehicle which carries them. If this conclusion is confirmed, the name of the drug should more

properly be *analgesine* or *nervine*. When, however, it is desired to diminish organic oxidation, antipyrin will be found of frequent application.

As to its antiseptic action, he thinks this will find numerous applications, since this effect is manifest from small doses, while it is but slightly toxic. He suggests that the good results which have been obtained from its use in the advanced stages of phthisis, are due to the double action of antipyrin upon tissue changes and upon fermentation.

In the discussion which followed the reading of M. Robin's paper, M. Verneuil stated that he believed antipyrin capable of rendering very great service in the treatment of septic surgical fevers; that, at least, was the conclusion which he drew from his employment of it in two cases then under treatment, in which very decided benefit had followed the use of the drug.

Abscess of Brain; Trephining; Recovery.

Barr (*Arch. of Otol.*, xvi, 2) reports a case of this kind in a boy, nine years old, who had had an offensive discharge from the right ear for a year. Three weeks before admission into the hospital he was seized with severe pain in the affected ear and side of the head, accompanied by a hot and dry skin, and followed by vomiting and drowsiness. These symptoms continued for four days; the vomiting then ceased, but the pain and drowsiness remained. Eight days from the commencement of the symptoms he had a severe rigor, which lasted fifteen minutes. He had six rigors before admission to the hospital, and the pain and drowsiness persisted. There was a perforation in the upper part of the tympanic membrane, from which pus escaped. Firm pressure over the mastoid produced pain. Barr opened the mastoid cells by chiseling through the cortex behind the auditory canal, and injected a weak solution of carbolic acid through the antrum and tympanic cavity out by the external meatus, and also in the reverse direction. A small quantity of pus and caseous *débris* was washed out. A drainage tube was introduced into the orifice in the bone, and iodoform used as a dressing. Twice a day afterward an antiseptic solution was forced through the opening and drum in both directions. Two days later he had a rigor, and the symptoms returned. Five days later there was a sudden and copious discharge of pus from the ear. All the symptoms subsequently became worse, and ptosis of the right upper lid appeared, and it was decided to trephine the skull. The middle ear was washed out with an antiseptic solution, and the scalp and neighboring parts carefully cleansed with turpentine and methylated spirit. A half-inch disc of bone was removed from the squamous portion of the temporal, at a point an inch and a half above and half an inch behind the center of the external auditory meatus. When the dura was opened and turned aside, the brain tissue immediately bulged into the osseous cavity, and rose above its external level. A hollow needle was inserted into the brain, and, after it had penetrated about three-quarters of an inch, there was a sudden escape of foul gas, accompanied by a bubbling sound and the escape of some fluid. The needle was inserted a little farther, when pus of an offensive odor flowed out. The aperture in the brain tissue was enlarged with a forceps, and portions of necrosed brain tissue were removed. The cavity was then washed out with a saturated solution of boracic acid. Pus continued to ooze from the wound, and an aperture was then drilled into the base of the skull, just above the osseous boundary of the external auditory meatus, involving the squamo-petrosal suture. The dura mater was here intact. It was opened and the abscess reached. A stream of boric acid solution was passed through this aperture so as to wash out the cavity of the abscess, and it made its exit freely by the upper opening. The current was then reversed. Chicken-bone drainage-tubes were introduced into both apertures, and the parts were thickly covered with boric acid powder and dressed with sublimated wood-wool pads. The wounds were dressed about once a week. The softened brain tissue at the seat of the upper opening in the skull soon presented a mass of granulations, which increased in size and rose into the aperature in the bone, uniting with the layer which formed on the exterior of the skull. They two soon became blended, and cicatrization rapidly progressed. The child increased in flesh rapidly, and was at the end of six weeks quite well. Three months after his admission all secretion had stopped in the ear, leaving a dry perforation behind. A vulcanite shield was fitted over the upper aperture in the skull, the lower one having completely closed.—*N. Y. Med. Journal*, Dec. 17, 1887.

—A young woman in Kansas City has been semi-unconscious for several days, as the result of a sudden and vigorous inhalation from a bottle of hartshorn, which she supposed to be one of cologne.

HEALING UNDER BLOOD-CLOT.

It is one of the most thoroughly rooted principles of the antiseptic method in surgery that all hemorrhage must be checked and all blood-clots must be removed from a wound before it is closed. Ligatures, torsion, compression, chemical and mechanical styptics are resorted to in order to prevent the slightest bleeding, or oozing of blood, from the surface of a wound, because some of the most distinguished surgeons regard the presence of the smallest coagulum as imperiling healing and offering a favorable soil for the multiplication of the germs of suppuration and of septicæmia. In addition to this, the use of drainage tubes has been regarded as almost indispensable to good surgery, and complicated forms of suture have been devised to prevent the presence of the smallest cavity in which blood might accumulate after a surgical operation. As recently as 1882, Von Bergmann—perhaps the most eminent German surgeon now living—delivered an address before a congress of German medical men, in which he presented with great force, and backed by his great authority, the principles we have just mentioned.

It is true that every surgeon must have observed in practice that many wounds, in which it was impossible or difficult to get rid of all clots or of all hemorrhage, did not fail to heal; that, on the contrary, they sometimes progressed without interruption to a speedy healing. But, it remained for SCHEDE, of Hamburg, to describe and recommend a method of treating wounds diametrically opposite to that founded upon a fear of blood-clots. About the middle of 1886, he published in the *Deutsche med. Wochenschrift* a paper on what he called "Healing under the moist blood-crust." In this paper he described a large series of operations, including forty resections of joints, one resection of the wall of the chest, forty-seven other bone operations, twenty open operations for club-foot, and twenty-four removals of tumors—in which he secured results as good as can be claimed for any method now known.

Such results challenge the most careful consideration, and it is interesting to know that further experience has confirmed Schede in the conviction that a blood-clot, so far from being dangerous to a wound, may be very useful to its healing. And now DR. A. SIEPMANN, of Hagenau, comes forward with a series of operations in which he followed Schede's method with the very best results. His paper, which is published in the *Deutsche med. Wochenschrift*, December 15, 1887, contains a sufficiently full account of his operations, and strongly supports Schede's claim that his method is simple, easy of execution and conducive to the comfort of the patient.

The details of Schede's method may be summarized as follows: At the conclusion of an operation the larger vessels are ligated and the wound is thoroughly irrigated with a 1–1000 solution of corrosive sublimate; then, if an Esmarch's bandage has been used, this is relaxed, and any vessels which spurt are tied, no smaller vessels being touched. After this the Esmarch tube is tightened again, and the wound is irrigated a second time. Then the wound is sutured, the sutures being placed close together at the

lower part of the wound, and at the upper part from a half to three-quarters of an inch apart. The object of placing the upper sutures so far apart is to enable any excess of blood or serum to escape; but this must not be considered a form of drainage; because it takes place at the top and not at the bottom of the wound. After the sutures are secured the wound is covered with an impervious material (protective) and the part is surrounded with antiseptic gauze and antiseptic pads, in layers, and is supported with splints and bandages, if necessary. The after treatment consists in removing an upper layer of the dressing, if blood or serum comes through it, and replacing it with a dry layer, after disinfecting the surface of the one below it.

In this method it is expected that a wound will become filled with blood; and this is found to become organized and to form the basis of a reproduction of tissue, which in some cases has been very astonishing. The progress of a large number of cases treated in this way has been as good as could have been secured by the most careful control of hemorrhage and the most perfect drainage and antisepsis; and the method is so much more convenient for the surgeon, and so much more comfortable to the patient, that it is deserving of extended trial in this country. We commend it to the attention of our readers as especially applicable to railroad surgery, as well as to the operations of resection and exsection of bones and the removal of large tumors. Its advocates in Germany lay stress upon its applicability to army surgery, a fact which is more pertinent to the conditions of European nations than to those of our own more fortunate land.

HEEDLESS TALK BEFORE CHILDREN.

Some time since, a horrible story came from the South that two children, whose parents had discussed in their hearing the details of the execution of a criminal, immediately afterward put in practice what they had heard upon their baby brother, whom they promptly hung by the neck until he was dead. And now comes a similar story from Alabama that a half-witted boy, who had witnessed the killing of animals for food, soon afterwards took his brother and sister, aged respectively four and six years, to the slaughter pen and cut their throats; after which he returned and told his mother what he had done.

These stories forcibly illustrate a wrong which is often committed by parents, in talking before them of subjects which are unfit for children's ears, and of which they are apt to think children have no conceptions. As a matter of fact, children use ideas as they use tools—audaciously and without the restraints which older persons put upon them. With tools they often injure their bodies, and with ideas they sometimes injure their bodies and almost always their minds. It is not only when they thoughtlessly carry into practice such cruel suggestions as were put in their heads by what they heard in the instances cited above, that they are led to disaster by heedless talk in their hearing; but also when they receive ideas which they apply falsely to their own experiences, and which lead to mental distress or confusion, in waking or in sleeping moments. Any one who has reflected upon his early life must recognize the fact that, waking and dreaming, children are often made unhappy, or led into sin, by what older people say in their hearing without a due regard to the way in which they may understand or apply it.

For the sake of children, then, older people should be extremely careful how they talk before them, so that they shall receive from their elders no ideas but such as are calculated to increase their happiness or improve their morals.

COLORED SOUNDS.

The statement that sound should have color may seem paradoxical; but when the fact is borne in mind that all the organs of sense are developed from the same layer of the blastoderm of the ovum—the epiblast—and that all sense perceptions are probably but translations of the mechanical impressions produced by vibration, it will not seem incredible that one organ of sense may,

within certain limits, translate the impressions it receives in the language of another organ.

There are perhaps few persons who have not noticed that certain impressions upon the tactile nerves of the skin are accompanied by distinct ideas of taste, or that certain tastes, caused by unirritating substances, are accompanied by impressions of pain. And it will not surprise those who have had this experience to be told that there are individuals who, on hearing certain sounds, have an impression of color. The fact was first placed on record, we believe, by Verga, in 1865, and has been studied since then by Lausanna, another Italian, and by Nüssbaumer and other German investigators. More recently, J. BARATOUX, in the *Progrès Médical*, Dec. 10, 1887, has published an interesting paper on the subject, going over it very thoroughly and giving an admirable history of it.

This subject is so interesting that we call the attention of our readers to it in the hope that some of them may be able to contribute facts illustrative of it. We live in an age when the study of mental phenomena is assuming very important relations to science, and anything which may throw light upon the inter-dependence of different parts of the cerebro-spinal system is of a more than passing value. There is no lack of theories in mental science; but there is still room for facts. And it may be that the readers of the REPORTER can contribute some facts bearing upon what is called "color hearing."

CRITICISM.

Mr. Stephen Fiske, in *The Writer*, October, 1887, discusses a phase of journalistic criticism which has no direct bearing upon medical matters, but which involves a principle as important in them as in any other. This is the principle, we may say, of rectitude. He contends that the best rule for the critic is to tell the truth, with discretion, with delicacy and with generous sympathy. To this, all right-thinking critics must agree. It is a simple rule, though by no means an easy one to observe. The opportunities of one who occupies the position of a critic are such that he is under great temptation to indulge his malice, if he be maliciously inclined, or to withhold just condemnation if he be timid, partial or mercenary.

The critics of medical journals are as human as any other class of critics, and as liable to err from simple human frailty or for unworthy reasons. But they, as well as all critics, should strive to use their office honestly, sincerely and without fear or favor. They should remember that they often control public sentiment, and can do much to secure a generous reception for what is deserving, or a proper condemnation of what is wrong or foolish. To hold the balance true is not always easy, and sometimes it is very hard. But every critic should endeavor to do this with the best judgment he has, and with a due regard to what may be excused by a good intention, even though it be marred by an unfortunate execution. The great fault of the criticism of this day is not too great severity; it is rather too great leniency, or even favoritism. Books, and papers, and men, and public performances are apt to be praised with a want of discrimination, which suggests that by no means all critics have in mind the rule which Mr. Fiske formulates. The principle of charity is stretched too far, and the critic seems to have a mind more to please the subject of his criticism than to inform the readers of it as to the real value of what he is criticising. Such a course works a double wrong: it deceives those who rely on the critic, and it encourages and multiplies the number of those who put forward work which is inefficient, careless or ill-designed.

Such critics are no friends to the general reader, although they may get the credit of being more good-natured than those who regard their office as a serious one, and think more of their responsibilities than of their comfort or gains.

—Diphtheria is reported to exist to an alarming extent in Newark, N. J.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY; NINETY-SEVENTH ANNUAL SESSION, JUNE, 1887. 8vo, pp. 186. Manchester, N. H.: Printed by John B. Clarke, 1887.

Judged by this handsomely printed volume of Transactions, the State Medical Society of New Hampshire is a body in which good sense and good feeling are admirably blended. The report of its proceedings, at the annual meeting in 1887, is very pleasant reading; and the papers presented are more than usually interesting. It appears that in New Hampshire the State Medical Society exercises a salutary control over the admission of men to practice, and has the power of revoking licenses for just cause—a condition of affairs which we wish prevailed in every State in the Union.

In going through this volume we began to note a few passages for quotation; but their number multiplied so fast that we find it impossible to do them justice. It will, however, be no reflection upon the merits of other papers if we call especial attention to the interesting papers of Dr. William Childs, on Thirty Years' Experience in Obstetrics in a Country Practice; of Dr. G. A. Sanborn, on Homœopathy; of Dr. W. S. Leonard, on Non-Professional Prescriptions; and to the Address of Dr. G. D. Towne before the Medical Graduating Class at Dartmouth. The latter is so full of common-sense and uprightness that it might be read with profit by all who are just entering, or who have recently entered, the medical profession.

NITROUS OXIDE; ITS PROPERTIES, METHOD OF ADMINISTRATION AND EFFECTS. By S. H. GUILFORD, A.M., D.D.S., Professor of Operative and Prosthetic Dentistry at the Philadelphia Dental College. Small 8vo, pp. vii, 94. Philadelphia: Spangler & Davis, printers, 1887.

The author of this little book does not need to justify its production by the statement in his Preface, that the last practical work upon the subject, published in this country, has been out of print for sixteen years; for it would be a very good book indeed, no matter how recent, which would make this one superfluous. It contains an admirable summary of the history, properties, effects, method of manufacture, and modes of administration of nitrous oxide gas, together with instructions in regard to the precautions to be observed in administering it, the manner of operating when it is used, and the measures to be adopted in case an accident follows its use. In addition, the author gives a good account of the legal complications to which those who use anæsthetics are liable, and the best way to avoid or to escape from them.

It is interesting to note his statement that nitrous oxide is so safe an anæsthetic that only four deaths have been attributed to its administration in this country, and that all of these were probably due to impurities resulting from imperfect preparation of the gas. In regard to the use of a combination of nitrous oxide with some other anæsthetic, such as ether or chloroform, the author has had no personal experience; but his acquaintance with the experience of other practitioners leads him to the belief that such a combination, properly made, is safe and may have some advantages over nitrous oxide alone. In this connection he expresses a very sensible objection to the use of proprietary considerations, the ingredients of which are unknown; and, under the head of "legal considerations," he says, that in case death followed the use of an anæsthetic of a proprietary or secret character the operator could hardly escape a legal penalty, because it would be justly held that his ignorance of the character of the ingredients would cause any effort at counteracting the unfavorable effects of the agent to be made blindly and unskillfully.

In reading this book carefully we have detected but three points in regard to which we would suggest an amendment, one on page 58 (*note*), where the author speaks of the recurrent laryngeal nerve as the recurrent pharyngeal; another on page 59, where we think it would be better to make some statement as to the quantity of nitrite of amyl to be used to counteract heart-failure; and the third on page 74, where the method of thrusting the lower jaw forward by pressure upon the rami, when the base of the tongue obstructs respiration, might be described and recommended.

Having said so much about this book of Dr. Guilford's, we need hardly add that we regard it as one of great value, and calculated to be of great service to all who have occasion to use nitrous oxide gas.

Pamphlet Notices.

Progressive Muscular Atrophy Beginning in the Legs. By J. B. Marvin, M.D., etc. From the *Practitioner and News*, July 24, 1886.

Report on Progress in Medicine. By J. B. Marvin, M.D., etc. From the *South-Western Medical Gazette*. 24 pp.

Recent Advances in the Treatment of Pulmonary Consumption. By Solomon Solis-Cohen, A.M., M.D., Consulting Physician to the Jewish Hospital, Philadelphia, etc. From the Transactions of the Medical Society of the State of Pennsylvania. Vol. xix. 14 pp.

De las Fracturas del Cráneo y de la Trepanación. Por el Dr. D. Enrique de Areilza, Medico por opposición y Director del Hospital Minero de Triano (Vizcaya). From *Revista de Ciencias Mèdicas de Barcelona*, 1887. 78 pp.

—Cases of progressive atrophy of the muscles beginning in the upper extremities are not uncommon; but cases beginning in the lower extremities are rare. Dr. Marvin's pamphlet recounts the history of an interesting example of this rarity, with a good description of the disease, as Erb understands it.

—Dr. Marvin's report on Progress in Medicine, read before the Kentucky Medical Society, June 14, 1887, contains a brief review of contemporaneous opinion in regard to bacteriology, heart disease, fever, antipyretics and phthisis. In regard to the latter he describes his own experience with Bergeon's method, which he thinks of moderate value.

—Dr. Cohen has written an excellent paper upon a subject of the greatest importance. It is true that the theme is somewhat hackneyed; but its treatment in the pamphlet before us is so sensible and, we believe, so sound, that we think no one would go amiss in getting a copy of it and studying its pages with care. The sum of Dr. Cohen's suggestions is that consumption is essentially a condition of malnutrition; and that feeding—super-alimentation—is the most important part of its treatment. He believes that Bergeon's method is of decided value under certain stated conditions. Inhalation of compressed and medicated air he thinks of great value, as also iodoform, iron and creasote, given internally.

—Dr. De Areilza's pamphlet contains the histories of twenty-nine cases of fracture of the cranium, seven of them illustrated with reproductions of photographs of the heads of the patients. In addition to the author's accounts and comments on these cases, he devotes a chapter to the subject of cerebral localization, another to the indications for trephining—in which, we think, he takes sound ground—another to the secondary effects of compression of the brain, another to the late irritative effects of cerebral traumatisms, and another to the *technique* of the operation of trephining. In a final chapter Dr. De Areilza studies the mechanism of indirect fracture of the cranium (*contre-coup*), and concludes that they are to be explained logically only on the theory of the elasticity of the skull—the bursting theory—so well advocated by Messerer in Germany, and, we may add, by Von Wahl in Russia.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—Four new medical journals have appeared in Vienna during 1887, viz.: the "*Internationale Klinische Rundschau*," the "*Klinische Zeit-und Streitfragen*," edited by Prof. John Schnitzler; "The *Centralblatt für Physiologie*," edited by Prof. Exner; and the "*Klinische Studien aus der Hydrotherapeutischen Abtheilung der Allgemeinen Poliklinik*," edited by Prof. Winternitz.

—*The Writer* is the title of a monthly magazine for literary workers, published in Boston, price $1.00 a year. It is an admirable magazine, full of interesting and instructive matter for those who write; and we think it would be found entertaining by all who read with a literary motive.

—*Woman* is the title of a monthly magazine published in New York; price $2.75 a year. The first two numbers contain a variety of interesting reading. It is intended chiefly to chronicle woman's work, and to furnish suggestions helpful to women, in their work. The motive seems to be excellent, and so far the execution of the project has been fairly good. The character of some of the advertisements warrants the suggestion that, if the publishers desire the support of sensible and upright people, they might aim to make this journal truthful from cover to cover.

—The *Health and Home Library*, Vol. I, No. 1, has been sent to us with a request that we express our opinion of its value. It is to be published quarterly, each number to contain no less than 100 octavo pages. It is issued in Chicago; price $1.00 a year.

It is hard to judge motives, and it is possible that this venture in the already weedy field of journalism may be prompted by a motive deserving of respect. But the first fruits of the venture is an apple of Sodom—fair in appearance, but nauseous to the taste. As an illustration of the quality we may mention only an article by the editor upon "Woman, her Ailments and her Sorrows," which is disgusting, when it is remembered that the periodical containing it is addressed to the laity. We find other faults in this publication; but have not space to allude to them. As we have been asked to express our opinion frankly about it, we do so in saying that it is, perhaps, the most wretched pseudo-scientific publication we have ever seen.

—*Medical Classics* is the name of a periodical purporting to be a medical magazine, published once in two months, in New York, price $1.00 a year.

Its characteristics lead to the suspicion that it is mainly intended as an advertising medium, and published in the interests of a manufacturing company of New York. Its chief literary attractions are a set of articles on monsters, copied from a book published in 1579, and several others on matters of sexual interest. There is reason to believe that it has little circulation except what it secures by gratuitous distribution. This distribution is not limited to medical men. We happen to have learned that the issue of December, 1887, was sent to a number of lawyers in this city, unasked, and not marked as specimens, and that its contents impressed one of them so that he inquired, after looking through it, "Where is Mr. Comstock?"

—The Senate of Michigan University has adopted a memorial tribute to their late colleague, Dr. Alonzo B. Palmer, who has served the University with distinguished ability for more than thirty-five years. He had a large influence in shaping the general policy of the Medical Department, and contributed very materially to its unbroken success. It was his good fortune to see the college which had started as a feeble organization steadily develop into one of the largest and most prominent of the medical colleges of the country, and to realize that this was largely due to his efforts. Dr. Palmer contributed many essays of interest and value to the literature of medicine. He also published "Lectures on Homœopathy" in book form, and a text-book for schools entitled "Temperance Teachings of Science," which has had a wide circulation. The crowning work of his life was the publication of a complete treatise on "The Theory and Practice of Medicine," in two large octavo volumes. In the International Medical Congress, which recently met at Washington, he occupied the position of chairman of the Section on Pathology; in the American Medical Association he was chairman of the section on the Practice of Medicine.

Correspondence.

Antipyrin—Help from the Reporter.

Editor of the Reporter,

Sir:—I have had some apparent good results from the use of antipyrin in pertussis, used in doses of from two to five grains three times a day. My opportunities for testing the treatment thoroughly have not been sufficient. I therefore trust I may hear something further from those who read this, and have an opportunity to try the remedy.

As an illustration of how a physician may often be benefitted by a good medical journal, and just at a time when he can best appreciate it, I relate the following: A short time ago I received the Reporter, which contained an editorial on the Hypodermic use of Strychnia in Heart Disease. At the time I read the article I was treating an old man, 60 years old, who had mitral disease, and was suffering with loss of compensation in the heart and the symptoms usually following it. I had used such preparations of digitalis as I could get, which were not the best; but irritability of the stomach supervened, and I was obliged to use hypodermic injections of morphia, $\frac{1}{8}$ grain, and atropiæ, $\frac{1}{150}$ grain, each night, in order to procure sleep and to relieve the distressing dyspnœa. As I had no suitable preparation of digitalis for hypodermic use, and as it increased the irritability when given by the stomach, I used strychnia, as directed in the editorial referred to, with great benefit; and, I believe, had my patient been placed under favorable conditions *otherwise*, I might have saved his life, or at least prolonged it.

As it was, the patient was greatly debilitated and did not take his bed until too weak to sit up or walk; he died after three weeks' illness. However, with the "hint" in the columns of the Reporter, I was led to try the strychnia, and satisfied myself of its utility. Before using the strychnia hypodermically, I had given pellets of nux vomicæ internally.

The next number of the Reporter, after the one referred to, contained an article on "Laparotomy in Gunshot Wounds of the Abdomen." At the very time when I received it, I saw the case of a young man with a pistol wound of the abdomen who died before an operation could be performed. The reader may term this a coincidence, but I have had similar coincidences to occur many times in the ten years I have taken the Reporter, and often they came as a valuable relief just at a time when I had apparently exhausted my resources, and knew not where to look for another. As Dr. Bennett suggests, we want clinical reading and practical information. The city physician may keep posted on the advances of medical science by continued association with or among eminent men in the profession, and by improving the opportunities and advantages of associations; but the country doctor must look to his journals if he keeps posted; for in these days of rapid progression the text-books soon grow old, and many things that are good are replaced by something better.

Yours truly, W. N. Sherman.

Kingman, Arizona, Jan. 9, 1888.

A Correction.

Editor of the Reporter,

Sir:—Is not the reference to the report of Drs. Wood and Formad, mentioned on page 721 of the Reporter (Nov. 26, 1887), a mistake? You have it, "Appendix A.—Report of the National Board of Health for 1887." Should it not be "*Appendix No. 1.—Report of the National Board of Health for 1881.*" No appropriation has been made for publishing the Reports since that of 1885, and even if there were, that for 1887 could scarcely be issued so soon. Please correct error in the Reporter, if error it be.

Respectfully, L. H. Cohen, M.D.

Quincy, Ill., Jan. 2, 1888.

[The error in our statement was a typographical one. The date should be 1882, instead of 1887. The correct description of the paper is "Appendix A.—Report of National Board of Health, 1882."—Editor.]

Artificial Eyes for Horses.

Editor of the Reporter,

Sir:—Where is the best place to get artificial eyes for horses?

Yours truly, B. F. D.

[Our answer to this question has been unavoidably delayed. We cannot say where the best place is; but Messrs. J. Kannofsky & Co., 369 Canal Street, New York, make a specialty of this line of goods.—Editor.]

Pronunciation of -itis.

Editor of the Reporter,

Sir:—What is considered the proper pronunciation of -itis in gastritis, hepatitis, etc.

John Hill, M.D.

Vincennes, Ind., Jan. 11, 1888.

[Both eye-tis and ee-tis are "considered" proper. What *is* proper depends upon whether the speaker consistently pronounces his Latin in the broad English way, or not. If he does, then he may say bronch-eye-tis; if he does not, then he should say bronch-ee-tis. —Editor.]

Notes and Comments.

How to Make Koumiss.

The *National Druggist*, in answer to the question, "how is koumiss made?" publishes the following directions for its manufacture: Fill a quart champagne bottle up to the neck with pure milk; add two tablespoonfuls of white sugar, after dissolving the same in a little water over a hot fire; add also one-quarter of a two-cent cake of compressed yeast. Then tie the cork on the bottle securely, and shake the mixture well; place it in a room of the temperature of 50° to 95° F. for six hours, and finally in the ice box over night. Drink in such quantities as the stomach may require.

It will be well to observe several important injunctions in preparing the koumiss, and they are: To be sure that the milk is pure; that the bottle is sound; that the yeast is fresh; to open the mixture in the morning with great care, on account of its effervescent properties; not to drink it at all if there is any curdle or thickening part resembling cheese, as this indicates that the fermentation has been prolonged beyond the proper time. Make it as you need to use it. The virtue of koumiss is that it refreshes and stimulates, with no after reaction from its effects. It is often almost impossible to obtain good fresh koumiss, especially away from large towns. The above directions make it possible for any physician to prescribe it.

The Isolation of Phthisical Patients.

Dr. Brown-Séquard, says the *Med. Press and Circular*, December 7, 1887, has just been calling attention to the necessity of isolating phthisical patients, on the ground that the disease has been shown to be transmissible during grouping together of patients affected with the disease. The evil results of breathing a bacillus-laden atmosphere are perceptible, he alleges, not only in the persons in attendance, but in the patient himself, whose end is thereby hastened. For this purpose he suggests a system of ventilation, analogous to that devised to carry off the products of gas combustion, and doubtless in special hospitals something of the kind might be practicable. Unfortunately, the vast majority of phthisical people are not in hospitals, but cooped up under circumstances which conduce in every way to the progress and dissemination of the disease. The suggestion is one of those which would be valuable were it only practicable.

The International Medical Congress.

The *Medical Press and Circuar*, December 28, 1887, says: The great event of the year in the medical world was certainly the Ninth International Congress, which took place at Washington, in September. The period of organization was a stormy one. A vigorous protest on the part of the medical practitioners of the United States against the exclusive privileges, arrogated to themselves by a powerful clique of the best known men in the Eastern States, led to a violent rupture, which, for a time, menaced the very existence of the Congress. Thanks, however, to the bold and concerted action of the dissentients, who had with them the vast majority, if not the most illustrious members of the profession, the reorganization was satisfactorily accomplished, and the Congress, though its lustre was dimned by the unfortunate disputes and the obstinate hostility of the defeated party, was numerically a brilliant success. So far as one can form an opinion, the scientific value of the meeting was equal to, though it cannot be said to have surpassed that of its predecessors. One great result of the abstention of the best known specialists, etc., was to bring into relief the really sterling qualities of some provincial men, who displayed a knowledge and a science very much in excess of what one might have been led to expect.

The London *Lancet*, December 31, 1887, says of the Ninth International Medical Congress: "The success of the Congress, in spite of adverse circumstances and prognostications, is a matter of congratulation."

Urine Fever and Toxic Urine.

Mr. Reginald Harrison, F.R.C.S., Surgeon to Liverpool Royal Infirmary, in the course of his Lettsomian lecture on Some Points in the Surgery of the Urinary Organs (published in the *Med. Record*, Jan. 14, 1888), lays down the following propositions, which embody his conclusions with regard to the production of "urine fever" and toxic urine:

1. That the presence of urine in relation with a recent wound is necessary for the production of what I have spoken of as urine fever.

2. That mere contact of urine with a wound is not sufficient for its production.

3. That the retention of fresh urine within the area of a recent wound is almost invariably followed by its development in a greater or lesser degree.

4. That where urine is placed under such circumstances as have been last mentioned,

the liability to the development of urine fever is greatly diminished when it is sterilized by local or general means.

5. That the retention of fresh urine, blood, and the débris of damaged tissue in the confines of a recent wound for a certain time, at a temperature of somewhere about 100° Fahr., could hardly be possible without chemical changes taking place in the constituents referred to.

6. That there is a common origin for urine fever is rendered probable by the uniformity of the symptoms attending it, which, though differing in degree, are identical, whether following a surgical operation or an accidental wound.

A Case of Cerebral Tumor.

A case of cerebral tumor, admitted into St. Bartholomew's Hospital, under Dr. Andrew, was described by Dr. Ormerod at a meeting of the London Pathological Society in December, 1887. He also showed the skull partially perforated in numerous places by the new growths. The patient, a man, was unconscious for more than a year before death, life being preserved by artificial feeding through the nose. The holes in the skull were due to small soft tumors sprouting from the brain, and a large abscess was found post-mortem in the left tempero-sphenoidal lobe.

The Conviction of Dr. Cross for Murder.

The *British Medical Journal*, December 31, says: "A most painful impression has been produced in Ireland by the conviction of Dr. Cross, a retired surgeon-major, for the murder of his wife by poisoning. The convict had a *liaison* with the governess, whom he married a fortnight after his wife's death. Mrs. Cross had been ill for over a month, and was attended by her husband, who certified that she died of typhoid fever. His subsequent hasty marriage appears to have aroused suspicion. The body was exhumed, arsenic in poisonous quantities was found, and there was no trace of typhoid fever. It was proved that Cross had bought a pound of arsenic for sheep-dipping purposes a year ago. The defence was that the deceased was in the habit of taking arsenic for her complexion, and it was suggested that a small bottle which was found in her press after her death, and which was thrown away, contained the poison. The only witness examined for the defence was the prisoner's sister. After conviction, he protested his innocence of the crime. The convict is a man of property, and moved in the best society." The doctor was executed.

Long-Lived Medical Men.

The London *Lancet*, Dec. 31, 1887, speaking of the death of medical men during the year 1887, says: "Dr. Ogston, of Aberdeen, had been teaching medicine for more than half a century; and Dr. Walker, of Peterborough, who died at ninety-one, had been "qualified" for seventy-one years. At eighty he walked by night across fen and fields to operate for hernia in a humble cottage, with the light of a tallow candle. More wonderful still was the death of Dr. Neklewitsch, of Loske, in Poland, at the alleged age of 109, having seen a patient just a quarter of an hour before."

The *Medical Press and Circular*, Dec. 28, 1887, records the death of Mr. George Sylvester, M.R.C.S., Eng., who is stated to have been the oldest medical practitioner in England. He was born March 10, 1788, consequently was within a few weeks of completing his century.

Extirpation of the Spleen.

An enlarged spleen was removed in London, December, 1887, by Sir Spencer Wells. The solid portion weighed one pound fourteen ounces, after a great deal of blood had drained from it. The patient was an unmarried woman, 24 years old. The wound healed by first intention, and she was so well on December 21 that she was expected to return to her country home before the end of the year.

The Influence of Sensations on One Another.

Under this head Dr. Urbantschitsch of Vienna reports some curious experiments, the value of which must be left to future research to decide. His general conclusion is, that the excitation of one sense-organ increases the acuteness of the others. If a disk be regarded at such a distance that its color is indistinct, the hearing of a sound will bring out the color. The beating of a watch is heard more clearly with the eyes open than with the eyes closed. Red and green increase auditory perceptions; blue and yellow weaken them. The fact that we listen to music with our eyes closed is due to other reasons, and also to the fact that the *ensemble* appears best when the tones are not at their clearest. Smell, taste and touch are open to the same influence. Red and green increase the sensitiveness of each of these senses; yellow and blue weaken their sensitiveness. Touch and temperature have a reciprocal influence. If one tickles the skin and plunges it into warm water, the

tickling ceases; if into cold water, the tickling brings out the feeling of cold. These observations are regarded as showing the same re-enforcing action between sensations as has been shown to exist between motions, and as offering a mode of explanation of those curious associations between colors and sounds so insistent in some minds.—*Science*, Dec. 30, 1887.

Philadelphia County Medical Society.

The Philadelphia County Medical Society held its business meeting and annual election of officers January 18, 1888. The treasurer, Dr. L. K. Baldwin, reported the receipts of the year as $2368.74, and the expenditures $1446.88. There are 504 members in good standing. The publication committee presented a volume of the year's transactions to each member. The expenses of the committee for the year were $728.33.

Arrangements were made for the entertainment of the State Medical Society, which meets in Philadelphia in the spring.

Frederick W. Pavy, M. D., F. R. S., and Lennox Browne, F. R. C. S., both of London, England, were elected honorary members, and sixteen others as active members.

Delegates were elected to the American Medical Association, and to the Medical Society of Pennsylvania.

The officers elected for the year 1888 were: President, J. Solis-Cohen; first vice-president, W. W. Keen; second vice-president, E. T. Bruen; secretary, S. Solis-Cohen; assistant secretary, A. C. W. Beecher; treasurer, L. K. Baldwin; censor, W. W. Welch.

The Brains of Celebrated Men.

The *Lancet*, Jan. 7, 1888, states that at the Société de Psychologie Physiologique, M. Manouvrier read a report upon the brain of the late Dr. Bertillon, the eminent statistician, and compared it with the brain of Gambetta, which had been studied by Mathias Duval and Chudzinsky. In weight Gambetta's brain was below the average, only scaling 1290 grammes (about 44¼ ozs.). That of Bertillon exceeded the usual weight, reaching 1394 grammes (about 47¾ ozs.). It is now admitted that, other things being equal, the weight of the brain is in proportion to the intelligence of the individual, and, moreover, the greater the intelligence the greater the absolute and relative development of the frontal lobes. A comparison of the brains of Gambetta and of Bertillon shows that the former is smaller, more particularly in the anterior portion, less so posteriorly, and that the temporal region is even larger. Now, the qualities of the two men were diametrically opposite. Gambetta was active and loquacious; Bertillon was reticent and retiring. Although an admirer of oratory, he had always failed as a speaker. In Gambetta's brain the circumvolution of Broca is extremely developed; in Bertillon's it is reduced to its most simple expression. Bertillon was in his youth left-handed, but he became ambidextrous later in life. The third frontal circumvolution on the right side (the speech centre of the left-handed) is larger than the corresponding one on the left side.

Freedom of Practice of Medicine in Germany

A correspondent of the *Medical Press and Circular*, Dec. 28, 1887, says: One of the burning questions of the year has been whether practice shall be free or not. But this is scarcely the whole question. It is difficult for all medical men in Germany to earn a livelihood as matters stand at present. A large number of irregular practitioners and quacks thrive, and there is a feeling abroad that, if these were suppressed by law, the money now diverted would return to its legitimate channel. Such a law could, and probably would, be passed if the profession were unanimous in demanding it; but it could not be passed alone. It would certainly carry another with it, making attendance on the sick compulsory. Any medical man, on receiving an urgent summons to visit a patient, would have no choice; the law would oblige him to go. Only those who know what the old law of compulsory attendance was have any idea of the irksomeness of it, and there has been, therefore, for some time a lively discussion as to the merits and advantages of the two systems. At present, those who are in favor of freedom of practice are in the majority; but it may be that increasing difficulty in making both ends meet will turn the scale.

Tribute to Three Brothers.

The Philadelphia *Ledger*, January 13, 1888, says: Dr. Robert Nebinger, whose death is announced this morning, is the last of three notable Philadelphia brothers. They were all noted for their intelligence, their benevolence, their public spirit, and their good citizenship; all three had been druggists first and then graduated physicians; all three were men of handsome personal appearance and fine manners; all lived to mature manhood, and yet lived and died unmarried. Dr. Andrew Nebinger, the eldest and second to pass away from this world; Dr. George

W. Nebinger, the second in seniority, but the first to die; and Dr. Robert Nebinger, the youngest and last to survive—leave memories that will be long cherished and honored.

The Action of Antipyrin in Epilepsy.

M. Georges Lemoine, in a paper on the action of antipyrin in epilepsy, sums up his conclusions as follows: Antipyrin is without action in the majority of cases of epilepsy, but nevertheless gives good results in those cases which belong to the following categories: (1) Epileptics in which the attacks are influenced by menstruation. (2) Epileptics who only have suppressed attacks. (3) Epileptics with migraine.

A daily dose of thirty grains suffices in the majority of cases, and its employment can be kept up for a long time without any danger to the patient. There is no advantage in doing this, however; because patients become habituated to its use. It should be reserved for the period when the crises occur, and is to be preferred to the bromide of potassium in the cases just indicated.—*Gazette Médicale de Paris*, Dec. 24, 1887.

Printing with Reference to Eyesight.

Several of the French railway companies, and other public bodies, have resolved on having their printing done on green instead of white paper. The reason for the alteration is that they believe the combination of white paper with black characters endangers the eyesight of their work-people. Black on green has always been recognized as a good combination, and many railway tickets are so printed. — *Druggist's Circular*, January, 1888.

Benzine in Making Suppositories.

A correspondent writes to the *Druggist's Circular*, January, 1888, recommending benzine as an agent in making suppositories without the aid of heat. He rubs the medicinal ingredients thoroughly with the cacao butter and then drops benzine into the mass, a very little at a time, and is thus able to bring it to pilular consistency. Lycopodium is used for dusting and the suppositories are either rolled or gently forced into a mould. They harden rapidly. Ether may be used instead of benzine, our correspondent says, but he prefers the former.

Borate of Ammonium.

Borate of ammonium has been found by Professor Lashkevich of great value in phthisis. Internally he gives five grains three times a day in solution, either alone or combined with codeia, hyoscyamus, or other sedatives. This he finds produces a marked effect on the expectoration, and in some cases where the affection had only reached an early stage, he observed a distinct diminution of the pyrexia. The solution was also employed with advantage as an inhalation, reducing the expectoration, and alleviating irritating and painful conditions of the mouth and throat.—*British Medical Journal.*

Sulpho-Benzoate of Soda in Antiseptic Bandages.

Heckel stated before the Paris Academy of Medicine, Nov. 14, 1887, that he had found sulpho-benzoate of soda an excellent thing for antiseptic bandages. The solution employed for the bandages was of a strength of 15 to 20 grains to a pint of water.

A Useful Hair Tonic.

Castor oil	1 pint
Alcohol	1 "
Tincture of cantharides	1 oz.
Essence of bergamot	℥ij

Color with alkanet. Allow to stand for two days and filter.—*Chemist and Druggist.* (Probably any ordinary coloring matter, such as logwood, will do as well as alkanet).

Prescription for Rachitis.

The following is from the *Progrès Médical*, Dec. 3, 1887:

Phosphorus	gr. $\frac{1}{8}$
Oil of sweet almonds	ƒ℥viiss
Gum arabic (powder)	
Sugar (powder) of each	℥iii ¾
Distilled water	ƒ℥xss

M.—Two or three teaspoonfuls, in coffee, a day.

Elixir of Saccharin.

A convenient fluid preparation of saccharin for dispensing purposes is:

Saccharin	grains 24
Bicarbonate of sodium	grains 12
Rectified spirits of wine	fl. drachm 1
Distilled water	fl. drachms 7

Rub the saccharin and bicarbonate of sodium in a mortar, with the water gradually added. When dissolved, add the spirit and filter. Twenty minims contain 1 grain of saccharin. This is sufficient to flavor a four ounce mixture.—*Am. Druggist.*

Eczema of the Eyelids.

Laille recommends in the *Union Médicale* the following:

℞	Acid. acetici (crystalized)	gr. iii
	Aquæ laurocerasi	ƒ℥v
	Glycerini	♏ lxxv

M. Sig.—To be painted on daily with a brush.

NEWS.

—Small-pox has appeared in Wilmington, Delaware.

—Dr. Dixon, Professor of Botany in the University of Edinburgh and Regius Keeper of the Botanical Gardens, died suddenly, December 30, 1887.

—Dr. H. Augustus Wilson has been elected Professor of Orthopædic Surgery, and Dr. Alexander W. MacCoy, Professor of Diseases of the Throat and Nose, in the Philadelphia Polyclinic and College for Graduates in Medicine.

—Among the inmates of the Connecticut State Hospital for the Insane, at Middleton, is a man who hasn't spoken a word for twelve years, except one morning, when he remarked to an attendant: "I guess I'll throw my bait over the other side of the boat."

—Dr. John Gordon, a cousin of Lord Byron, died at Texarkana, Ark., Dec. 14, 1887. Dr. Gordon, who had been in this country for over forty years, and was a prominent Southern merchant, claimed to be the right heir to the Earl of Aberdeen.

—The Society of Medical Jurisprudence in New York city, on January 12, appointed a committee to present to the Legislature a bill making it a criminal offence to use the name of a physician as recommending the use of any patent medicine without his consent.

—A Congress is to be held at Madrid, under the auspices of the Spanish Gynæcological Society, in April or May, 1888. It will consist of three sections—obstetrics, gynæcology, and "paidopatia" (diseases of children). The general and sectional work of the Congress will occupy eight days.

—The Section on Practice of Medicine, of the New York Academy of Medicine, met at the rooms of the Academy, Jan. 17, 1888, and chose Dr. R. C. M. Page, chairman, and Dr. G. B. Fowler, secretary, for the coming year. Dr. S. De Jager read a paper on "Objections to Williams's Pneumatic Cabinet."

—In Italy, France, and Germany, a pharmacist, in addition to his responsibilities as a citizen, has others which make him a sort of public official. As an illustration of this fact may be mentioned the condemnation, by a court in Italy, of a number of pharmacists to pay a fine of 50 francs each, and to suspension from the practice of their business for three months. The cause of this heavy punishment was that when cholera broke out at Messina they deserted their posts and fled to places of safety. As each one returned he was arrested, and after trial condemned as stated.

—A Detroit druggist was recently accused of employing an unregistered assistant. The evidence was clear, a witness being ready to testify to having purchased of the assistant, in absence of the proprietor, an ounce of Rochelle salt. When sworn, however, the witness stated that he had purchased an ounce of *sugar of lead*, a poison which the law allows grocers and others to handle without restriction, and the case had to be dismissed. Why the witness swore to a falsehood we can only conjecture, unless it was simply an aggravated instance of heterophemy.—*Phar. Era.*

—It is reported from San Antonio, Texas, that a man named Calvin Pease, while blasting in a well, Dec. 28, 1887, touched off a short fuse of a dynamite cartridge, which exploded before he got out of the well. When brought to the surface it was found that one of his hands was blown off, the other badly mangled and the entire front part of his skull, from the eyes to nearly the crown of the head, carried away, leaving most of his brain exposed, but not injured. His eyes were also destroyed. Notwithstanding these remarkable injuries Pease has not lost consciousness a single minute since the accident. He eats heartily, converses cheerfully, and sleeps well, though some opiates are necessary.

—We learn from the Government Health Report that the number of cases of small-pox in San Francisco during the year 1887 was 168, and during the period from January 1 to 5, 1888, there have been 25 cases. Of these, 14 were among the Chinese. The disease was brought to San Francisco early in May by one of the China steamers, but did not prevail to any extent until November. On December 29 the disease was declared to be epidemic by the board of health. All cases, on being verified, are immediately sent to the hospital, with their bedding and clothing; the premises are fumigated, and all persons living in the neighborhood are vaccinated if possible. Vaccination offices have been opened in various parts of the city. No children are admitted to the public schools without having been previously vaccinated. Over thirty thousand vaccinations have been made at the office of the board of health during the past six months. Under the circumstances, the board of health is of the opinion that the disease will soon be stamped out.

HUMOR.

A STUTTERING SON OF HAM, whose wife was threatened with a miscarriage, rushed into a doctor's office, and in an excitable manner, demanded his immediate attention.

"What is the matter, Pompy?" queried the doctor.

"My-my-my wi-wi-wi-wife is-is a-a-a-about to-to mis-mis-mis-misconstrue."

DOCTORING A COUGH.—Wife—I am so worried about that cough of yours, John, dear.

Husband (fondly)—Don't be foolish, little one. It is a mere nothing.

Wife—It may be a mere nothing, John; but I do wish you would see the—insurance man, to-day.—*New York Sun.*

THEY HAD ASKED Dr. Sandblast, the eminent surgeon, to carve the festal fowl, and he stood over it with the carving-knife delicately held in first position. "The incision, you will observe, gentlemen," he began, dreamily, "commences a little to the left of the median line, and—oh, excuse me, Mrs. Parmalee—I thought I was in the—the—*may* I help you to a little of the femur?"

A SAD-LOOKING man went into a drug-store, and asked the druggist if he could give him something to drive from his mind thoughts of sorrow and bitter recollections. The druggist nodded, and put him up a mixture of quinine and wormwood and rhubarb and epsom salts, with a dash of castor oil, and gave it to the man; and for six months he could not think of anything except new schemes for getting the taste out of his mouth.

AN EXPERT.—"I suppose," said the stranger, as the group of tired travelers were discussing the nature of the malady from which the German Crown Prince is suffering. "I suppose I have had as much experience in the treatment of malignant and rapid throat troubles as any in America." "Ah, you are a physician, then?" "No," said the stranger, "not exactly, but for six years I was chairman of the Texas vigilance committee."—*Buffalo Journal.*

A GIRL OUT WEST accidentally swallowed a trade dollar, a few months ago. Her life was at first despaired of; but after some six weeks' treatment and the use of a powerful specific for trade dollars, a number of red sores broke out all over her body, and, when these were opened, a copper cent was found in each. At the last report eighty-four cents had been removed in this manner, and her physician was hopeful of recovering the whole amount swallowed, perhaps with interest.

A SUNDAY-SCHOOL TEACHER began his questioning at the end of the old year with the query: "Are you better than you were last year?" A good many of the little fellows had replied "Yes, sir"; but a croupy boy on the back seat had the courage of his convictions. "I hain't no better nor I ever wuz," he said, "but," he added by way of softening the harsh statement, "I got'e sorest froat of anybody in this class—I—I—I—most got dipferia."—*Youth's Companion.*

A SHREWD SPECULATOR.—Omaha man—Having a boom down South, eh? Southern man—Biggest kind of a boom; city lots selling like hot cakes.

"I am glad to hear it. Some years ago I foresaw that the South would have a big boom and I bought considerable property down there." "You did? That beats me. When was it that you concluded the South would become a centre of immigration?" "When the tariff was taken off of quinine."

OBITUARY.

DR. OBED BAILEY.

Dr. Obed Bailey died at West Chester, Pa., January 10, 1888, aged 87 years. He was a native of Chester county and a graduate of Jefferson Medical College, where he completed his student life in 1830. He practiced his profession for many years in Chester county and in Wilmington, and while in the latter place held many offices of trust and honor. He was a graduate of Yale College. He leaves a son, one of the oldest surgeons in the U. S. Army, Colonel Elisha J. Bailey, now stationed at San Francisco. Another son is Lieutenant Colonel Joseph C. Bailey, surgeon U. S. A., and Medical Purveyor, now stationed at New York city.

There have been no Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Jan. 15, 1888, to Jan. 21, 1888.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Jan. 21, 1888:

C. B. Goldsborough, Surgeon, to proceed with insane seaman from Chicago to Government Hospital for the Insane. Jan. 16, 1888.

F. C. Heath, Assistant Surgeon, to proceed to Buffalo, N. Y., for temporary duty. Jan. 21, 1888.

Omitted from Previous Lists:

G. W. Stoner, Surgeon, to proceed to Wilmington, N. C., Georgetown and Charleston, S. C., Savannah and Brunswick, Ga., Fernandina, Jacksonville, and Pensacola, Fla., as Inspector. Dec. 30, 1887.

WHOLE No. 1614.] FEBRUARY 4, 1888. [VOL. LVIII., No. 5.

ERCILDOWNE.

A Private Medical Hospital for Mental and Nervous Diseases.

Situated at Wissinoming, in the suburbs of Philadelphia, eleven miles from Broad Street Station, on the New York Division of the Pennsylvania Railroad, and within two minutes walk of the station. Commodious in structure, richly furnished, having large, airy rooms, thoroughly ventilated and heated and cheerful sun parlors front and rear. It covers twenty-nine acres of lawn and gardens, and is free from malaria. Each case receives the attention and study given to private practice, and physicians can continue as consultants in cases committed by them.

Clinical Lecture.

ON COLD ABSCESSES.

BY PROFESSOR TERRILLON,
SURGEON TO THE SALPETRIERE, PARIS, FRANCE.

(Translated by E. P. Hurd, M.D.)

Gentlemen:—We shall take up to-day the study of an affection which you will frequently have occasion to meet in practice, and the treatment of which has made such important advances the past few years; I allude to cold abscesses.

Cold abscesses, as you know, comprise two great varieties: the *cold abscesses* properly so called, due ordinarily to a *local tuberculosis* of the cellular tissue; and the *ossifluent abscesses*, having their origin in a disease of the bone, which is almost always of tuberculous nature. The first variety will now claim our attention.

You have recently had an opportunity of observing in our wards a remarkable example of cold abscess in one of our patients, a female, aged sixty years, and for the past two years or so very feeble. This woman presented at the inferior and external part of the forearm a small rounded tumor, quite firm and resistant at first, which insensibly increased in size, and by degrees softened so as to manifest a very evident fluctuation. All this took place without apparent inflammation, without pain; the patient experienced hardly any impediment in the movements of the wrist and thumb. For a long time outward applications of tincture of iodine were made, but to no purpose. Resolution was not obtained; the same condition of things continued for several months without change. Latterly, however, whether under the influence of traumatism, or some other cause not apparent, the little tumor has been the seat of a slight inflammatory flushing.

It was under such conditions that the patient was first treated. When fluctuation was detected, a puncture was at once made in the tumor, that the nature of its contents might be ascertained; and then, by a narrow incision, the flow of pus was favored. Every day we practiced carbolic injections into the cavity of the abscess, without effecting a cure. This absence of result, despite the treatment employed, should not surprise you. We shall find in the very constitution of the abscess the cause of this want of success.

In fact, if you examine the walls you will see that the cavity is limited by a thick indurated tissue, and that, notwithstanding the previous treatment, there remain two fistulæ through which flows a yellowish, sero-purulent liquid. The peripheral swelling does not tend at all to disappear. Moreover, the local examination still shows an elongated and hard tumefaction over the radius which completely masks the subjacent bone. Pressure causes a serous pus to ooze forth.

In view of these phenomena, we may advance two hypotheses: either we have to do with a cold ossifluent abscess, or else the underlying bone is sound, and what we really have to contend with is a simple cold abscess, or, more strictly speaking, a local, suppurating tuberculosis.

To elucidate the nature of the lesion, and to enable me to act more energetically on this local disease, I made a large incision, and through this free opening I was able to explore the cavity. I have shown you that it was lined with fungous vegetations, of gelatiniform aspect, but slightly vascular, and easy to destroy by scraping. Below the abscess sac the bone was found with its periosteum

intact; everywhere, however, at the bottom of the cavity, and in the *culs-de-sac* connected therewith, the finger moved back and forth over a thickened œdematous membrane, of fibrous aspect; finally, all around, the tissues were indurated. Note, moreover, that the abscess was situated between the skin and the deep, much thickened aponeurosis; that the tendon of the palmaris longus, smooth and intact, traversed it throughout its whole length. After having opened this abscess, I removed the fungosities with a curette. I cleaned out the entire cavity, so as to expose the fibrous and whitish envelop of the sac; then I stuffed it with iodoform gauze, and surrounded the whole with a layer of absorbent cotton.

From all this, bear well in mind the mode of evolution of this tumor: first, the appearance of a tumefaction over the inferior extremity of the radius; a little later, softening of the tumor and fluctuation; then, after an insufficient opening, the production of two fistulæ, and thereupon the discovery of the fungosities lining the sac and keeping up the suppuration. Such is the ordinary evolution of cold abscesses.

Let us now study, more in detail, their anatomical characters. The histological examination of the walls shows that there has been going on in them an alteration of a quite special nature. On section of the wall, we see that it is constituted of three distinct layers: there is first the internal surface, uneven, rough, studded with anfractuosities and fungosities; little fragments become detached and fall off into the interior of the cavity and mingle with the pus which is there. This first layer is easily destroyed by scraping. It is not so with the second layer, which is composed of embryonal cells; it is more solid and resistant. The third layer is formed of a still firmer membrane, constituting a solid zone; this is the limiting membrane.

Histological examination shows the walls to be infiltrated with tubercles. In fact, upon the internal layer we find an accumulation of embryonal elements which have become caseous and surround the giant-cell, which is characterized by its multiple nuclei and the irregularity of its prolongations; and here and there we observe the capillaries obliterated. The middle layer is infiltrated with embryonal tubercles; that is to say, with little microscopic nodules, the centre of which is occupied by a giant cell, and around which are massed embryonal cells; more externally, larger cells, called epithelioid cells, complete the tubercle nodosity. These corpuscles are separated from each other by an infiltration of embryonal cells, and present themselves under the form of little round nodules, either apart or running together. Virchow has also shown that a certain number of tubercle nodules exist without the giant cell. These two layers, which I have here considered separately for facility of description, are not in reality as distinct as I have represented them; but are intimately blended. The interior of the sac is at first organized; but, by reason of the caseification of the tubercles and of their disaggregation, it undergoes softening, falls into detritus, and little by little the work of destruction invades the successive layers, and the cavity of the abscess augments.

The most external layer of the cold abscess is constituted by heaps of embryonal cells agglutinized together, but without any organization, and studded here and there with tubercle nodules. It is not rare, in this variety of abscess, to meet with anfractuosities and prolongations of the principal cavity under the form of secondary pockets (*boyaux*), which present the most varied forms and the most complex ramifications. From a clinical point of view, these prolongations have a capital importance: they explain the difficulty of cure, for they constitute just so many secondary foci which become the point of departure of new tuberculous outputs, and, consequently, of new cold abscesses.

Let us now study the relations of these abscesses with the tissues in the neighborhood. In many cases the sac is easily separable; it may be shelled out when it is quite limited, especially at the start. Later, however, are developed those prolongations of which I have spoken, which invade the muscles and tendinous sheaths. These render enucleation impossible. In other cases you will find large partitioned chambers, due to the fact that these secondary prolongations of the sac have spread and undergone development at the same time that their communication with the sac by degrees has become larger. You must then expect to find the greatest variety in the configurations of these abscesses.

As for the contents of these abscesses, these ordinarily consist of thin diffluent pus, which is almost of the nature of serum, mingled often with flaky particles formed of the detritus of the internal surface, and floating in the liquid. These flaky particles explain the difficulty which one has in evacuating these abscesses by aspiration, even though a large-sized trocar needle be employed.

The contents of these abscesses are always subjected to a high degree of tension; hence they escape with violence at the moment of incision of the walls.

If the liquid diminishes in quantity and tends to disappear at the same time that the solid elements are very abundant, we observe a variety described under the name of *caseous abscess*, the cavity of which is filled by a whitish mass, more or less thick. Lastly, in very old abscesses, there may take place a slow absorption of the solid elements; the liquid part, on the other hand, accumulates; and when these abscesses are opened, there escapes a clear liquid, sometimes charged with cholesterine. These are the cold abscesses which had undergone transformation into cysts.

You see, gentlemen, by all these details, that the appearances under which cold abscesses present themselves are multiple. It is always in reality the same affection, but the processes of evolution may be different.

Such were the most exact notions which histological examination furnished us concerning the structure of these abscesses, when a recent discovery showed us another characteristic element, having a still greater value. In the first of these abscesses, in the fungosities which line them, and even in the substance of their walls, you will always meet with the bacilli characteristic of the disease (Koch's bacillus). A careful examination, practiced after staining the elements, enables one easily to recognize these special microbes under the form of little rods. They are often difficult of discovery, and numerous preparations may be necessary to bring them well out; yet it is rare that they cannot be found, especially when sought for in fresh preparations of the fungosities of the internal surface. I have, however, seen cases where the most patient and the most minute researches have not disclosed the characteristic bacilli, first described by Robert Koch.

In this event, gentlemen, we have another criterion, which is still more absolute than the preceding, namely, the proof furnished by inoculation. You introduce into the cellular tissue, or, better still, into the peritoneal cavity of a hare, a few drops of pus, or a portion of a fungosity; soon afterward you see develop a general tuberculosis which is certain to kill the animal. This inoculation test unfortunately demands quite a long time, one, two or three months, before furnishing the proof required; but it is ordinarily very conclusive, and when the results are positive, it may be regarded as well-nigh infallible.

We shall see, when we come to treatment, what rôle is to be ascribed to those bacilli which are the real source of the disease, and alone capable of perpetuating it. We shall see that it suffices to destroy them or prevent their development, if we would arrest the course of the local disease and effect a sure cure. Now that you know the anatomical constitution of cold abscesses, I shall describe their clinical evolution. At the start, they present themselves under the form of tumors, sometimes very superficial, bunched or rounded. When they are of small dimensions they do not give any fluctuation. This variety is designated under the name of *scrofulous gummata*. At the end of several weeks, sometimes of several months, you may discover at the centre a point of fluctuation. In such cases, the growth is ordinarily slow, progressive, and takes place without provoking any pain. When the abscess undergoes softening, the skin may become perforated, and there is seen to issue by a fistulous orifice a sanious pus, charged with detritus and clotty lumps. Sometimes the termination is different; there is an absorption of the various elements of the abscess, and the cure is effected spontaneously, but this rarely happens. After opening of the abscess, when there is no longer any tension in the sac, there is no longer any tendency to extension of the lesions, but the internal surface of the abscess cavity is irritated, and the fungosities become more abundant and more voluminious. These prevent the coming together of the walls; they sometimes protrude through the fistulous orifices which continually give issue to a purulent oozing. These fungosities are but slightly adherent; they readily yield to the curette, but they invade the entire cavity of the abscess, and even its prolongations.

Despite the name of cold abscess, applied to these swellings, when their course is rapid, there may be a local elevation of the temperature of from four to six-tenths of a degree, and you will then see a slight inflammatory zone on the external surface. Sometimes the general temperature of the patient shows a slight rise. This is especially apt to be the case after a slight contusion, or when the abscess threatens to burst.

It remains for me now to indicate the treatment of cold abscesses. When you have only the scrofulous gummata to deal with, even supposing pus to have formed, but the tumor to be of little size, and the general health not to be suffering but improving, you are warranted in waiting; a cure is possible by resorption, or after one or two aspirations.

When the abscess is larger and more extensive resorption is impossible, the sac should be freely opened, for puncture by the aspirating needle or trocar, in these conditions, is generally insufficient; the liquid is, in fact, soon reproduced by reason of the want of vitality of the abscess walls. The best way, then, in these cases, is to interfere energetically, and to perform thorough ablation of the sac, as M. Lannelongue has indicated. This practice is certainly the best when the sac which limits the abscess can be readily enucleated. You then dissect out the sac, bring together again with stitches the soft, bleeding parts separated by the dissection, and put in a drainage-tube to facilitate the flow of liquids; thanks to the methodical compression of the antiseptic dressing, the tissues reunite, and the cure is soon complete. It is necessary, however, to take care to remove the prolongations of the cavity, a task often difficult of execution when the walls are thin and soft.

By another curative method, which is more particularly applicable where the sac cannot be removed in its totality (as is, in fact, most frequently the case), you open widely into the abscess and scrape the internal surface of the sac with a sharp spoon or cutting curette, taking care to destroy the fungosities; then the two surfaces are brought together with a stitch or two. If reunion seems impossible it is better to stuff the cavity with iodoform gauze, and protect the whole by an absorbent dressing, as I have done in the case of our patient. The cure is slow, but sure.

A third method consists in making a free opening and cauterizing thoroughly the sac with the thermo-cautery in order to destroy all the fungosities. You have then nothing but a large eschar, formed by the diseased parts thus profoundly modified. This method is slower, less active, and less energetic; therefore, I will only counsel it in a restricted number of cases. At the same time, the employment of the thermo-cautery has given me excellent results in a special variety of multiple cold abscesses, many instances of which I could cite, occurring in the fold of the groin, in the axilla, neck, etc. They present themselves under the aspect of little violaceous masses with numerous holes, giving to the region the appearance of a ball-sprinkler. In those cases where there exist multiple abscesses, diverticula, detachments of tissue, and fistulous tracts extending in different directions, total ablation is impossible, and curetting, which is ordinarily incomplete, has no efficacy. It will be necessary, then, to open up all the fistulous tracts, cauterize the fungosities, transform the multiple diverticula of the abscess into a sloughing surface, and bring into full view all the detached shreds of tissue. In this way only will you obtain complete cure.

The different modes of treatment which are now everywhere in fashion, and are absolutely safe, owing to the employment of Lister's method, and especially of the iodoform gauze with which the abscess cavity is stuffed, are likely to be in a measure superseded by a method lately devised by Mosetig-Moorhof, of Vienna, and recommended in France by Verneuil. This new method is chiefly applicable to large abscesses with huge pouches, in which a radical or bloody operation seems difficult or dangerous. Starting from the principle that iodoform is an excellent parasiticide, which prevents the development of tubercle bacilli, the Vienna surgeon conceived the idea of putting this substance in contact with the walls of the cold abscess, and in such a way as to attack the microbes in their innermost haunts, and to do this thoroughly and permanently. To attain this result, it is necessary to empty the abscess as thoroughly as possible with an aspirating trocar, and wash out the cavity with a solution of carbolic acid, in order to remove the caseous particles which may be too thick to run easily. After evacuation of the sac, a variable quantity (according to the size of the cavity) of ether is injected, holding in solution iodoform in the proportion of five per cent. The quantity of the liquid thus introduced in the largest sacs ought not to exceed four ounces, for fear of accidents which might result from the absorption of too great a quantity of iodoform. The liquid is allowed to flow out after a few minutes, but a certain quantity remains in the cavity. The surface of the latter is soon lined with a thin layer of iodoform. Under the influence of this agent the pain is moderate, and the reaction not severe; but the sac soon fills again with liquid and with gas, swells and becomes slightly painful. After a few days all irritation is allayed, and we see the liquid undergo resorption, and the cavity and the tumor growing smaller. One may, in some cases, obtain a complete cure after several weeks, often as the result of a single injection. When one injection does not suffice, the operation may be repeated after a month or six weeks; two or three suffice for the largest sacs.

You will find upon this subject important particulars in the writings of Prof. Verneuil, and especially in the monograph of one of

his pupils, Dr. Verchère, which was published in the *Revue de Chirurgie*, for 1886. I need only refer you for an example of this kind of surgical intervention to a patient, A. B., of this hospital, on whom I have practiced these injections.

This patient, a woman, aged seventy-seven years, large, lean and infirm, had on the anterior and inferior aspect of the right thigh, an immense cold abscess. It was thirty-five centimetres long, twenty-three wide, and contained four quarts of grumous pus. A first injection of three ounces of ether-iodoform solution caused but little reduction. After one month the abscess had diminished one-half. A new injection of two ounces produced a similar result.

At the present time, four months after the first injection, the abscess is barely as large as half a mandarin orange, and will, I think, continue to undergo decrease till it disappears.

This is, then, an excellent method, and not dangerous, generally succeeding; and I cannot too highly recommend it to you, for I have employed it several times with success.

Communications.

THE HYGIENE OF PHTHISIS.[1]

BY LAWRENCE F. FLICK, M.D.,
PHILADELPHIA.

In the beginning of the present century Dr. Willan, in his statistics on the diseases of London, gives the percentage of deaths from consumption in his private practice as about one in three; and says that the proportion in the general mortality reports for the winter months at that time varied from one-third to one-half. In 1880 the percentage of deaths from phthisis in England was 9141 in every 100,000, which indicates a marked improvement. This improvement is not due to a larger number of cures, but to a more successful prevention which follows in the wake of civilization.

It is scarcely disputed by any one at the present day that consumption is due to the bacillus tuberculosis. Concomitant with this doctrine is necessarily that of its contagiousness, and whoever accepts the one must accept the other. Heredity ought to be out of the question at the present day. It is an unreasonable theory, and at variance with all modern knowledge about the etiology of disease. Its complete eradication from the public mind is one of the first steps necessary in a sanitary crusade against phthisis. So long has it held sway, and so thoroughly has it been woven into our literature, into our ways of thinking, and even of acting, that it has actually become a remote cause of the disease. Men and women are daily dying victims of consumption, because they have not the courage to escape its clutches. Their grandparents or parents, their uncles or aunts, or somebody in their families has died of the disease, and it is a foregone conclusion that some day, sooner or later, they will die of it too. They are tabooed by society as foreordained victims, they are refused life insurance on the slightest pretext, and are at a discount in the marriage market unless heavily endowed by purse or landed estate. Their lives are one continuous worry lest the disease overtake them, and yet they do nothing to avoid it, or the depressing influences which lead to it. If they do finally succumb to the disease, their education and that of the public have been factors in its production. Somewhat akin and often confounded with heredity is the doctrine of predisposition. That some families are more apt to develop certain diseases than others is beyond dispute. What this predisposition consists in, and whether dependent upon the blood, the nerves, or tissues, is as yet one of the hidden secrets of nature. It is certain, however, that it can be transmitted for generations, and that, like complexion and features, it may go to only certain members of a family, may skip a generation or two and reappear, or may disappear entirely. It sometimes goes with one or the other sex, and sometimes accompanies certain complexions and features. Whilst it often exhausts itself by the laws of survival, it may also be generated *de novo* by the modes of life and habits of the parents. The tight-lacing girl, the pale-faced, dissipated young man, the overworked store girl and factory hand, the tea-drinking servant girl, the drunken father, the half-starved, badly clothed mother—these are some of the progenitors of predispositions of phthisis.

So much in brief about the theories on the etiology of consumption. Their consideration has been necessary in order to study intelligibly the means for its prevention.

Both in theory and practice we find that consumption, though contagious, is but mildly so. This is, in my estimation, not so much due to inefficiency of the bacillus tuberculosis as to the withstanding power of the lungs

[1] Read before the Philadelphia County Medical Society, January 11, 1888.

of most people. The bacillus tuberculosis never finds a nidus in a healthy lung—by healthy, I mean not only freedom from pathological change, but a strictly physiological condition in which every function is properly performed. Like the brain, I believe the lungs may be functionally abnormal, and yet there be no pathological change discoverable. There is a very close relationship between the functional abnormality of the lungs and the digestive apparatus, and, in a sequential way, the whole nutritive system. It is upon the stomach, then, almost as much as upon the lungs, that much depends in the prevention of phthisis. The stomach is usually the first traitor in the human economy. Through its derangement many diseases gain entrance into the body. When the stomach fails to perform its work, the lungs will soon do the same. A vicious circle is established, and they mutually derange each other. Malnutrition follows, and the lungs become a proper soil for the bacillus tuberculosis. Every care should therefore be taken to keep the stomach healthy, and to do this a sufficient and proper supply of food is necessary. Too much food is as injurious as too little, and improper food worse than either. When the stomach is filled with indigestible food, nutrition is not only withheld, but the stomach is unfitted for the proper performance of its work for some time thereafter.

It is generally in overfed and improperly fed people that we have what is called galloping consumption. Though apparently well nourished, their entire appearance is suggestive of too much foreign matter in the blood. It is from this class of people that the mortality list from consumption is kept so high in America, and it is chiefly the foreign element in our population which constitutes the class. The deaths from consumption in the United States are nearly twice as numerous among the foreign population and their children as among the children of the native born. In Rhode Island, according to the health reports of that State for 1880, one person in every 486 of native parentage dies of consumption, while one in every 286 of foreign parentage dies of the disease. According to the United States census reports for 1880, out of every 1,000,000 deaths, 242,842 males and 302,046 females die of consumption. This represents all nationalties and colors. Among the colored race every million deaths represent 248,179 males and 326,973 females as having died of consumption. Among people of Irish parentage 309,507 males and 375,636 females die of consumption to every one million deaths; and among people of German parentage the victims of the disease number 249,498 males and 254,958 females to every one million deaths. It will be seen that the largest percentage of deaths from the disease is among Irish immigrants and their children. This is usually ascribed to the change in climate. Ireland has a much damper climate than America, and therefore one better suited to the development of phthisis. The real cause for the larger mortality from consumption among foreigners, and especially among the Irish, is the change in diet. At home they have been accustomed to a plain, healthy diet, and when they come to this country they at once take to the varied heavy diet of Americans. Where they have eaten little meat at home, they eat it in profusion here. Where they have drank good milk and eaten vegetables at home, they drink teas and coffees and eat spiced food here. They soon become thorough Americans in their stomachs, and even outdo the natives. The consequences are indigestion, malnutrition, tuberculosis. The German, though frequently pursuing a similar course, is often spared by his characteristic thrift and economy. He partakes more sparingly of the good things that come in his way, because of his anxiety to prepare for a rainy day. His fondness for beer, a beverage which he manages to secure wherever he goes, may likewise have some influence in shielding him against phthisis.

Sufficient fresh air, sufficient food, and sufficient rest and sleep are the watch-dogs of health, and where they are on the alert consumption can never enter. Bacilli of tuberculosis may permeate the air, but they can do no harm. Could civilization reach such a stage of perfection as to make it possible for every human being to have all these, it would be in the power of everyone to avoid phthisis. Such a condition of things is, however, impracticable. It therefore becomes necessary not only to deprive the bacillus tuberculosis of its proper soil, but also to destroy the bacillus. This function belongs as well to the State as to the individual. Modern governments are beginning to appreciate the importance of preserving the health of their people, and are everywhere establishing health boards. As yet, however, they do not go far enough. Medical science has grown beyond the mere art of prescribing remedies; it has become a science of protecting man against disease and enabling him to attain his three score and ten. As government exists for the good of society, it ought to avail itself more extensively of so powerful a means to its end. The medical profes

sion should be represented in our government. There should be a department of medicine, as there is a department of agriculture, of justice, of finance, etc. Surely human lives are as valuable as those of dumb brutes, and we want protection as much against the invisible foes which threaten our health as the visible ones that threaten our hearths. Unfortunately, public sentiment has not yet been educated to appreciate sufficiently the importance and benefit of sanitary measures, to make such a thing practicable. Did such a department exist, and did physicians in good standing and with scientific attainments occasionally enter the field of practical politics and allow themselves to be returned to city councils and State and national legislatures, sanitary science might shed its light upon legislation and many existing hygienic evils be remedied; many social and commercial customs and practices which are daily generating predispositions to consumption by the thousands might be corrected. Plainer living would come through proper instruction upon the subject and the instillation of the necessary sentiment in our schools. Not only ought children to be taught what to eat and drink, but also how to prepare their food and what quantity they can take consistent with health. Nor should instruction upon the proper adaptation of food to the time of life be overlooked. Many children are already dyspeptic when their school days begin, and in their cases the benefit of instruction could only accrue to the second generation. The depressing influences of private vices in children and young people could often be averted by early instruction of the proper kind. Such instruction should, of course, come through the parents, but parents are themselves frequently devoid of the proper knowledge, hence the government might supply it to them by the free distribution of appropriate books. How many social and moral evils might be warded off were the proper knowledge brought to the thousands who would gladly avail themselves of it, were it within their reach!

Legislation might in a measure protect the weak against the oppression of the strong. One need only visit the parts of large cities where the poor live, and note the crowded, filthy courts, alleys and tenement houses; or take a stroll through a badly ventilated factory or retail store in which the employés are compelled to work long hours in unhealthy positions and with the most wretched accommodations for the ordinary demands of nature; or examine some of the articles of food and drink that are openly sold in shops and on the streets, to understand what could be done in the way of sanitary science by wise legislation. The remedying of such wrongs and oppressions would very much lessen the the mortality from consumption, by withdrawing the soil necessary for its development. But all this is mere speculation of what we may hope will take place in the future. For the present, we must content ourselves with discussing the weapons against the bacillus tuberculosis, which governments can use as they are now constituted.

The usual methods employed by our boards of health for combating disease are isolation and disinfection. Against consumption, isolation, if it were even practicable, would be both useless and cruel. It is a question in in my mind whether the existence of the bacillus tuberculosis is solely for the destruction of human lungs! In view of the universality of phthisis it is not entirely a matter of fancy to suppose that the parasitic life of the bacillus in man is incidental, and that it plays some useful rôle in the great chain of transition between organic and inorganic matter. It seems to be everywhere and to be wafted about by the air. Isolation could therefore not confine it, nor afford protection. The only benefit that could be derived from it would be the withdrawal of the relatives of patients from an atmosphere saturated with the germs of the disease and their protection against contamination by the sputa. This would be a poor return for the dreadful inhumanity of separating the poor victims for years from their relatives. The same results can moreover be attained by disinfection without isolation. With well equipped thorough boards of health and properly instructed laity, satisfactory protection could be secured to those who by family ties or otherwise are compelled to live in the same house with the afflicted. The house, and especially the room, in which the patient sleeps ought to be frequently disinfected with some suitable germicide, and particular care should be taken to disinfect the sputa. For the former purpose sulphur may be burnt or a spray of a strong solution of carbolic acid be used, and for the latter carbolic acid or corrosive sublimate solution be placed in the vessel that receives the sputa. To carry out these measures in practice, consumption would have to be placed upon the list of contagious diseases returnable to the board of health, and the present force of existing boards of health would have to be largely augmented. The beneficial results, however, would be ample compensation for the inconvenience and expense. That there would be

a marked decrease in the mortality from phthisis I have not the slightest doubt. Better opportunities, too, would be afforded to study the disease, as more reliable reports would be made and fuller statistics be gathered.

Health boards should, moreover, help to disseminate proper knowledge upon the subject. If ignorance is the parent of vice, it is certainly the grandparent of disease. It is a matter of daily occurrence that people who have consumption, and who are constantly expectorating infectious matter, fill positions in which they must necessarily contaminate the clothing, food and drink of others. There are consumptive tailors and dressmakers, consumptive cooks and waiters, consumptive candy-makers, consumptive bakers, consumptives indeed in every calling of life. These people do not suspect for a moment that they are spreading the disease, and take no precaution against doing so. They are often poor people who have to work for their living, and who as long as life remains in them have to earn its support. They do not even know that they have consumption, or at least they persuade themselves that they have not got it. They expectorate on the public highways, in church, at the theatre, at their places of business or work—in short, anywhere and everywhere that is convenient; and the sputa dry up and are carried into the lungs of others, or find their way into food and drink. First of all, people ought to be made thoroughly familiar with the infectiousness of the sputa, and ought to be taught how to disinfect them. This knowledge should come from the government through the boards of health. Physicians and public teachers can do much toward creating a proper sentiment, but they cannot convey the instructions in an authoritative and effective way. In the next place, no consumptive should be employed in any capacity in which he may contaminate the clothing, food, or drink of others. To obviate hardships in such cases, the government should make provision out of the public treasury for the maintenance of such people as have to give up their means of livelihood for the public good. Whether this be done by pension or by offering an asylum must remain for political economists to decide. No hesitancy is felt in spending millions for the resentment of an insult to our national honor, or for some commercial advantage. Why should not something be expended in the protection of our people against the ravages of a disease which in the United States carries off nearly a hundred thousand people annually? Small remedies will avail nothing with so great an evil. Our government should act, and act with gigantic strides. As regards individual effort to prevent the spread of consumption, it must necessarily be confined almost entirely to those who by predisposition are likely to develop it. They should not only lead strictly hygienic lives in every particular, but should avoid everything that might even remotely lead to the disease, and avail themselves of every weapon against it. The nearer they follow Nature, in its dictates as to how to live, the better. They must not revel in excess, turn night into day, overload their stomachs, overtax their brains, strain their physical endurance, and play havoc with their constitutions generally, as their more favored brothers and sisters do with impunity. They must lead correct, orderly lives, and be ever on the alert that their physical condition may not fall below par. As regards the weapons to be used against the disease, it may be well to pass some of them in review.

Climate has always been looked upon as an important factor in the production and prevention of consumption. Its importance, however, seems to me to have been much exaggerated. A non-porous soil is undoubtedly a contributing agent to the production of consumption, but not more so than of many other diseases. Consumption occurs in every country and every climate on earth, being modified in prevalency by the various modes of life. Vicissitudes of climate have really little to do with the disease. Those people who are most exposed to the weather seldom die of consumption, whilst those whose lives keep them indoors are its most frequent victims. Women, for example, die much more frequently of the disease than men. Nor does warmth or cold or altitude exert much influence. The colored people, who live largely in the warmer portions of the United States, have a higher mortality rate from consumption than the white people, the majority of whom live in the colder portions. In short, consumption prevails everywhere, no matter what the climate, where people are compelled, by the demands of society, to crowd together and live much indoors. The practical lesson to be drawn from these facts is that persons who are predisposed to consumption by reason of the lives of their forefathers, or the peculiar circumstances surrounding their childhood, ought to adopt a calling in life which keeps them out of doors and away from cities.

There is a popular belief that alcoholic drinks are powerful preventives of consumption. This, like all popular beliefs and superstitions, has undoubtedly some truth for its foundation. But, as is usual with the bastard progeny of desire, this grain of truth has grown into such immense proportions as to have become the stumbling-block of many. No one who has carefully studied consumption can have a doubt that there exists some relation between its production and the non-assimilation of hydrocarbons. Very many cases of phthisis have traces of sugar in the urine, and probably all of them have indigestion of heat-producing food. These symptoms frequently exist for months before cough and discernible local congestion sets in. As beverages containing a small amount of alcohol present a most readily assimilating form of the hydrocarbons, they no doubt, when properly used, buoy up the weakened system in its struggle against the bacillus tuberculosis, and often enable it to gain the mastery. But what is good in moderation is always hurtful in excess, and in this instance precipitates the very evil it might otherwise prevent. Excess of alcohol and the adulterating ingredients in alcoholic beverages derange the stomach, and thus by interfering with nutrition predispose to consumption. In this way a long life of hard drinking sometimes ends in phthisis.

A very noticeable fact in the mortality statistics of consumption is the predominance of women among its victims. This is in a measure due to their indoor life, but not altogether. The many accidents and diseases incidental to the physiological life of women greatly predispose to consumption. These are, however, nearly all of an avoidable character, and have their fountain-head in carelessness during the menstrual period and during the puerperium. Women should be taught from childhood that these are sacred epochs, and that during them nature demands rest and especial care. The Semitic six weeks' rest after childbirth is true to nature, and should be observed by every woman who becomes a mother. Lactation frequently predisposes to consumption, but usually in those cases which have made bad recoveries after confinement, and are in want of the proper food and care which are necessary for a nursing woman. Pulmonary gymnastics are powerful weapons against phthisis, and should be especially used by those who are unable to extricate themselves from the unhygienic surroundings and circumstances in which their necessities have placed them. Though the use of a gymnasium is very desirable for practicing these, it is not necessary. The principle involved is ventilating the unused air-cells, and any combination of forced respiratory movements that will thoroughly inflate the lungs will accomplish this. Gradually filling the lungs with air whilst retracting the shoulders and extending the chest, or taking a deep inspiration whilst extending the arms above the head and expiring whilst placing them parallel with the body, are two simple exercises which do all that is necessary, and can be taken without interfering with the most busy life or causing fatigue. A habit should be made of thus ventilating the unused portions of the lungs, and it should be done at times when the purest air can be secured. The most practical germicide that we as yet know of for the bacillus tuberculosis is fresh air, or, more correctly speaking, it furnishes the least favorable habitat for its development. A better oxygenation of the blood is, moreover, secured by such exercises, the circulation is stimulated, and, indirectly, the digestion and assimilation improved.

As regards the hygiene of phthisis, when the disease is once established, it is based upon the same principles as that for its prevention. Sufficient nourishing food, and sufficient fresh air, these are the *sine qua non*. The prime object in every case of phthisis should be to secure a good digestion and assimilation. Everything that is done should be done with this object in view. Good, nourishing, and easily digested food should be taken in abundance, and every care taken that the stomach be not deranged by indiscretions in eating and drinking, or by overloading. As soon as the body begins to nourish, the lung trouble will improve. As an aid to digestion outdoor exercise is very important. Without it the system cannot be made to use up a large quantity of food. Inasmuch as warm climates offer greater inducements to keep invalids out-of-doors, and make bedroom ventilation a little more agreeable, they are highly commendable to consumptives; but they are by no means essential to their well-being. A cold climate will do just as well if the patient has the courage to endure the discomforts entailed by it. It is much better that a comsumptive have home comforts in the worst climate in the world, than that he be compelled to undergo the tortures of boarding-house or fourth-class hotel life at a health resort. In all warm climates the houses are built for warm weather use, and no provision is made for the stray blizzard that occasionally comes along. Though the temperature may be very

equable from day to day, there is always a marked variation between day and night. In consequence of the rapid radiation of heat the houses become cool and damp during the night, against which there is likewise no provision, except in first-class modern hotels. In many places suitable food is difficult to obtain even at the most extravagant prices. All in all, the average person who has consumption had better remain at home, unless his home is in a large city, and then he should go into the neighboring country, where he can secure home comforts and plenty of suitable food. Let him dress warm, take outdoor exercise whenever he can, eat plenty of light, nourishing food, take ample rest and sleep, and he will get along much better in his native heath than he would with small means in the most model consumption climate. It is important that the entire body be warmly clad in cold weather. Either silk or woollen clothing ought to be worn next to the skin. The circulation should be kept equable throughout the whole body, hence the extremities ought never to be let get cold. When the feet get cold, the lungs become congested. Rubbing the body with a coarse towel has a good effect in equalizing the circulation. The ancients recognized this fact, and laid stress on it. "Balneum alienum est," says Celsus. Sponge baths, if carefully taken, will do good. They should, however, be taken in a warm room, and followed by a rest. Sea-voyages used to be highly recommended in the early days of medicine, and theoretically, at least, ought to be beneficial in the first stages of the disease. The ocean offers a pure atmosphere, and frequently the salt air stimulates appetite and improves digestion. In the advanced stages of the disease they are, however, impracticable, and should never be attempted.

Gypsy life, or travelling through the country by easy stages and camping-out, is most beneficial to consumptives, even in advanced stages. The ancients had their patients carried from place to place in chairs. In the territories most remarkable cures are brought about by this mode of living. Persons unable to walk are hauled in wagons on improvised beds, and it is astonishing what a revivifying effect constant exposure in the open air has. But, as said in the beginning of this paper, when consumption is once established it is rarely cured, and though much can be done to ameliorate the condition of the consumptive, the most important duty of the medical profession, at the present day, is to lend its aid in bringing about such a change in public and private hygiene as to give the disease less chance for development.

Civilization is the keystone on which the barrier to the progress of phthisis must be built; but it must be a high order of civilization, a civilization in which charity for our fellow-man is the guiding star—which teaches not only how to live, but how to let others live—which banishes want from the earth, gives everybody sufficient breathing space, and removes the foot of monopoly from the neck of the working-man and the goad from his side; which will remove morbid ideas about dress, society, customs, and education, and banish all vice and excess from the world. So long as the objects of man's existence are to live at ease, gratify every desire, and tower head and shoulders above everybody else in importance; so long as one-half of the human race must be without the necessaries of life in order that the other half may revel in excess; so long as crowded tenement-houses must tower in the sky in order to let palaces spread out on the surface; so long as soulless corporations can drive men to do more than a whole day's work for half a day's pay, and under circumstances and surroundings which are in conflict with every rule of health; so long as the rich lead and the poor follow in health-ruining fashions and customs; so long as children have their minds made morbid and their bodies ill-developed by school-cramming processes; so long, indeed, will consumption continue to be epidemic, no matter what progress scientific medicine may make.

REDUCTION OF THYROID DISLOCATION OF THE THIGH-BONE.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

I was called, May 10, 1887, to see a mulatto woman, 25 years old. She had been under the treatment of an itinerate female practitioner for two months; was said to have rheumatism. Liniments had been used freely, along with internal medication.

I found her unable to walk from soreness about the left hip and thigh. She could not use crutches, because the lame leg was two inches longer than the other. A glance at the deformity showed that the head of the thigh-bone was in the thyroid foramen. I could get no history of traumatism from either the woman or her husband, both declaring that they knew of no cause for the dislocation. But I learned from a neighbor that the woman had been thrown over a

fence by her husband about the time the lameness commenced.

After making my diagnosis I repaired to my office to study the dislocation on the skeleton. Here I found on laying it on its back on the floor, and placing the head of the femur in the thyroid foramen, that by bringing the dislocated bone across its fellow, that the trochanter minor came in contact with the spine of the ischium, making a fulcrum, by which the head of the bone could be lifted out of its false cavity and on a level with the acetabulum. My patient was quite thin, and I concluded that the dislocation could be reduced by a similar manœuvre, as I knew, from a vaginal examination, that the spine of the ischium was quite prominent.

The next day, with the help of my partner, Dr. G. O. Morgridge (now professor of surgical pathology and of ophthalmology in the College of Physicians and Surgeons, Keokuk, Iowa), she was etherized, and placed upon a thin mattress on the floor. She was laid on the edge of it, so that the sound limb would hang over and be more out of the way. Seating myself beside her on a low stool, I grasped the knee and leg, keeping the latter fully extended, while Dr. Morgridge steadied the pelvis. The luxated thigh was now brought across the sound one, until the trochanter major became quite prominent, and it was judged that the head of the bone was lifted high enough to pass over the rim of the acetabulum. The femur was then pushed directly towards the articular cavity with a slight rotary motion, when it went in easily, but not with the snap usual in a recent dislocation, as the cup had been partly filled by granulations. It stayed there, and the patient made a good recovery after having an abscess of the thigh.

TYPHOID FEVER.

BY J. A. LONG, M.D.,
LONG'S MILLS, TENN.

In what I have to say on the subject of typhoid fever and its treatment I will confine myself to the facts as I have observed them in a long practice in this section—lower East Tennessee.

Typhoid fever first showed itself in the winter and spring of 1843–4, in an endemic form, under the various names of winter, *slow*, and *nervous* fever.

The onset of the disease is uniformly slow and tedious, the patient not being able to tell on what particular day he was taken with the disease, moping around for a week or ten days, complaining of little or no pain, but of weakness only, while he is not disposed to do any mental or physical labor; but is listless and dull, with sensations of cold or chilliness, or even a well-marked chill, recurring at irregular times during the first stage of the disease.

At this stage of the fever the tongue becomes coated with a white fur; it is smooth and glossy with its tip and edges red, and when the patient is told to protrude it, he invariably puts it out tremulously and may not withdraw it until told to do so.

The tongue undergoes many changes during the progress of the disease. If the fever runs a tedious course, the coat turns brown and becomes dry, and the upper layer of the mucous membrane peels off, leaving a fiery-red surface. Soon after this the coat begins to form anew; and this change may take place several times before the disease terminates in convalescence or death. During these changes the tongue presents a speckled appearance, and in grave cases it becomes black and deep furred, while dark sordes form on the teeth.

The pulse is generally small and accelerated, ranging from 90 to 120, according to the grade or stage of the disease, with a double or reacting beat.

Headache comes on during the second week and lasts for about ten days, with or without medicine, and then passes off, not being much influenced by remedial measures. This symptom is pretty uniform in typhoid fever. About the same time, or during the second week, the fever increases, the pulse becomes more accelerated, and an eruption of rose spots makes its appearance on the front parts of the chest and abdomen, and in a few cases it may be seen on other portions of the body. The rash makes its appearance at a certain stage of the disease, passing off at a later date. I have observed it at the commencement of the second week, and also as late as the end of the third week. In my experience it has been formed in ninety per cent. of all the well-marked cases of typhoid fever.

Delirium, which comes on in all medium and grave cases, is of a muttering character. It is unlike the delirium of most acute diseases in that the patient, in the midst of his mutterings, can be aroused when spoken to, and may answer one or more questions intelligently enough, and then lapse into the same state of derangement. In a very small percentage of the cases the delirium is wild, furious, and of a belligerent character; the

patient is hard to control and tries to force his way out of bed, resisting the kindly efforts of his attendants, even striking at those who oppose him; but such cases are the exception, and not the rule in typhoid fever.

The temperature in typhoid fever ranges from 100° to 105° in grave cases, and the gravity of the case is pretty accurately indicated by the range of temperature.

The abdominal symptoms in typhoid fever are among the most prominent of the disease. Diarrhœa usually commences early in the disease, and is more or less troublesome throughout its entire course. The discharges are generally green or greenish in color, and as a rule without smell. Their passage along the bowels is attended with a gurgling noise. If this latter symptom be not present, it is easily induced by pressure made upon the abdomen, and especially if made over the right iliac region. The bowels are more or less tympanitic in most of the cases, and this symptom is generally in proportion to the gravity of the case. Bleeding from the bowels is a common symptom in typhoid fever, and especially apt to occur when the too free use of purgative medicines, at any stage of the disease, has caused irritation of the ulcers of the small intestines, which are known to exist in every well-marked case of typhoid fever.

Typhoid fever as it shows itself in this locality is both infectious and contagious. This is certainly the case among persons who are at the age in which typhoid fever oftenest occurs (between ten and thirty years), and especially if they are exposed as nurses, or are about the sick room much of the time. Many instances could be cited in which young persons have gone a distance of miles to wait on a sick friend, and after returning home have been taken down in a short time with the fever, making new centers for the spread of the disease.

My experience is that typhoid fever seldom attacks children under ten years of age. I have met with but one case of typhoid fever where the patient was under ten, and that one was a child in its ninth year. From many circumstances that have fallen under my observations in practice, I believe that one attack of typhoid fever exempts the person from future attacks of the disease, at least as much so as in other eruptive contagious diseases. I am aware this is denied; but I think the denial is mainly founded upon faulty diagnosis. I have practiced medicine in the same locality for forty-four years consecutively, and I have never met with typhoid fever twice in the same individual. I have attended in the same family at different times, where the older children, in their teens and over twenty had the disease, and where the younger children, under ten years of age, were exposed as much as those who had taken it, but escaped entirely. Five years later I was called to the same family, and the younger children, who had grown up into their teens, were sick with typhoid fever, while some of the older children, still living at home, who were equally exposed to the same infectious causes, and also to the contagion of their sick brothers and sisters, entirely escaped the ravages of the disease.

Diagnosis.—The diagnosis of typhoid fever is plain and easy when its history, symptoms and course are carefully and patiently studied. The grouping of symptoms is remarkable in this disease: its slow, tedious and insidious attacks; the peculiar, dull expression of the face; the characteristic tongue and pulse, as described in this paper; the prominent abdominal symptoms, diarrhœa, bleeding from the bowels, epistaxis, rose-spots, etc. There is no disease that is likely to be mistaken for typhoid fever, but the typhoid type of many diseases; "and unless we distinguish between typhoid fever proper and the typhoid type in many diseases, there is an end to all philosophical diagnosis."

Prognosis.—Nothwithstanding, this fever is a terror wherever it makes its appearance, I believe there is no disease which has so strong a tendency as typhoid fever to terminate favorably if it is not aggravated by maltreatment. Whenever the time arrives in medical progress when typhoid fever is not regarded as belonging to the class of eruptive fevers, infectious and contagious, which cannot be cut short by the use of strong drugs, then its fatality will be lessened.

Treatment.—This should be strictly *eclectic* to be successful. Symptoms must be met as they arise in the case, with the mildest possible means at our command. The temperature is to be watched closely, and it should be kept in safe bounds, because it is *fever that kills*. This can be controlled by tepid sponging, with a little vineger in the water—not by ordering it attended to once, twice or a half dozen times a day—but by teaching the nurse to *keep the fever down* by going over the whole surface repeatedly, until it is completely under control.

In the stage of incubation the patient is liable to aggravate his case greatly by staying out of bed too long. One of the first things to be done is to request the patient to lie down and keep in bed, and as quiet as possible. If the weather is warm the linen should be changed at least every other day,

and in some cases this should be done daily. In cold weather the change should be made at least every third day by good, handy, sensible nurses. If the feet are inclined to be cold, they should be bathed in a mustard bath as warm as the patient can well bear it. This may be repeated every day, if necessary.

As soon as there are signs of ulceration in the glands of the small intestine—and this is one of the earliest symptoms—I put my patient upon an emulsion of turpentine, and do not wait, as most authors advise, until the tongue is dry and dark. This is giving the ulcers of the bowels all the headway possible. The emulsion I make of a solution of gum Arabic and turpentine, so that one teaspoonful contains one drop of the turpentine. This is given every hour, except when the patient is asleep. When he awakes, I begin again, counting the hours from that time. Other symptoms, such as diarrhœa, are met by the mildest means. In mild cases, Dover's powder answers a good purpose. In cases of bleeding from the bowels, acetate of lead and opium meet the indication.

Diet.—This is an important part of the management of typhoid fever. In the first stages of the disease I usually allow only toast-water, rice-water, toast, coffee, etc. Later, the diet can be cautiously increased. Fomentations to the bowels, when there is tympany, is an excellent manner of allaying irritation. I do not prescribe some *great thing*, but simply conduct the patient safely through the different stages of the fever.

—The Young Men's Institute of New York, a branch of the Young Men's Christian Association, has established a medical benefit club for the members of the Institute. Any member in fair physical health may join the club upon payment of the initiation fee of fifty cents, and the dues are only fifty cents for three months. Payment of these small sums of money entitles a member of the club to free medical service from a physician chosen and paid by the governors of the Institute, and to a discount of 25 per cent. on prescriptions compounded by any druggist designated by the physician.

The object of this club is not to make money, as is the case with many somewhat similar associations in England, but to assist the members of the Institute, which is actually a charitable concern, although every effort is made to keep this fact in the background, and to encourage a feeling of manly independence among its beneficiaries.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, January 11, 1888.

The President, J. Solis-Cohen, M.D., in the chair.

Dr. Lawrence F. Flick read a paper on

The Hygiene of Phthisis.[1]

Dr. T. J. Mays, in opening the discussion, said: I have listened with much interest to this remarkable paper, which expresses a view which I did not think existed to any extent in this city. The author attributes the existence of pulmonary phthisis to the bacillus tuberculosis. I do not think that such a view is borne out by the facts. If it were true that phthisis is propagated by contagion, those who are the most exposed to the disease should be those who would be most liable to contract it. The facts prove that this is not the case. Probably the best evidence of this is found in the history of Brompton Hospital, of London, when the report was made a few years ago. This hospital had been in existence thirty-six years. It has a capacity of nearly four hundred beds. The history includes all those who were connected with the hospital as physicians, nurses, etc., during this period. Not one case of the disease could be traced to the hospital as the source of contagion.

Dr. Brehmer gives some remarkable results in his book on the *Etiology of Pulmonary Tuberculosis*. He states that in the town of Görbersdorf, where his hospital is located, that the mortality rate of the native inhabitants from phthisis twenty years ago, at which time the hospital was established, was fifty per cent. greater than at present, notwithstanding that during that time there have been present about twelve thousand consumptive patients, who have freely mingled with the citizens. It also often happens that at health resorts for consumptives the physician himself is the subject of the disease, and yet, under such circumstances, frequently improves in spite of the presence of the tubercle bacilli. The author advocates a strict quarantine against the bacilli. Precisely such a quarantine was carried out in Naples for sixty years, up to forty years ago, but the results were entirely negative. In another statement the author is, I think, not borne out by facts. He states that females are more liable to the disease than are

[1] See page 135.

males. I have recently gone over an enormous amount of statistics, collected in this country and abroad, and they show that females are much less liable to the disease than males. The report of my statistics will be found in the *Medical News* of January 7, 1888. The fact that the disease is less frequent among females may be accounted for by the fact that they have a more extended apical motion than the male, and we know that consumption never occurs in any one who has a well-developed apical expansion. On the whole, one cannot help but be pleased with the paper; but while I admire it, I cannot agree with all the statements which it contains.

Dr. J. Daland said: I think it has been well ascertained that an hereditary predisposition does play an important influence in the causation of phthisis. With reference to the climatic treatment of phthisis, I do not think that this can be dismissed with the few words which the author has given to it. There seems to me to be no doubt that in the early stage of the disease, particularly in young men, that a change to a colder climate is of benefit. The disinfection of the sputa is a point on which sufficient importance is not usually placed. It is a matter of the greatest moment, and should be employed in every case of phthisis.

Dr. S. Solis-Cohen said: I believe that it was Mr. Spencer who thanked a certain philosopher for benefitting him by expressing opposite opinions in a forcible and eloquent manner. I can make my acknowledgments to the reader of the paper in similar language. I admire the suggestiveness and the vigor of his paper, but I find it almost impossible to agree with any of the theories advanced. As to the practice advocated, physicians of experience are all of nearly one mind; nor has Dr. Flick permitted himself to be led astray in this matter by his theories. The question of the omnipotence of the bacillus tuberculosis is one which deserves to be ventilated on every occasion. I have already to-night quoted the remarks of Dr. B. W. Richardson in another connection; but as I consider him the master-mind in medicine of the nineteenth century, I need offer no apology for again quoting him. He says, "What have we done, to be visited in the heavens above, in the earth beneath, and in the waters under the earth, with the *pestis bacillorum* which is now regnant?" Everything is bacillus. Dr. Richardson believes that it will not be long before the bacillus of pregnancy will be discovered. I think that Dr. Flick has himself given the strongest argument against the bacillophobic views he advances. The chain of events graphically described from several starting-points invariably concludes in—malnutrition and consumption. Malnutrition is the fundamental, the bacillus is the accidental. It may be that the bacillus does, when inoculated under certain circumstances, cause tuberculosis; there is some doubtful evidence bearing on this point which cannot be dismissed in a discussion of this kind. Even admitting that inoculating with the bacillus will cause consumption, there is no evidence that the inhalation of the bacillus will cause the disease. The inhalation of sputa and the inhalation of the bacillus are two different matters. The pus-cell and the coccus pyogenes are not at all synonymous. There may be in the mixture which goes to make up the sputum an element similar to those bodies which we know as the leucomaines and ptomaines, which, in a person predisposed and in low condition, may be capable of exciting the disease by interference with nutrition or otherwise. The evidence on all these points is very far from being clear. But granting, for argument's sake, that the microbe is one of the existing causes, we must still recognize, as the reader of the paper has pointed out, that the bacillus is everywhere present; and no matter how powerful are the means brought against it, they are incapable of destroying it or of dislodging it when it is once in the lungs. Even if we could destroy every bacillus in the lungs, at the very next breath the enemy is once more within the stronghold. Therefore the only rational thing to do to prevent consumption, whether the bacillus be a cause of the disease or not, is to build up the nutrition of the individual by the measures mentioned to-night and by others. We must utterly discard the misleading, and therefore destructive, idea that by bringing germicidal agents against the bacillus tuberculosis we can benefit our patients in the least. Treat the patient, and the bacillus will take care of itself.

The question of the marriage of those who inherit the tuberculous diathesis—and that there is such a diathesis universal experience goes to prove—is a very important matter, and, notwithstanding the views advanced, I think that every one of us should warn against the marriage of those whom we have reason to suppose would transmit such a woful inheritance. The question of baths in consumption is an important one. There are two methods of failure of function in consumptive patients which we must recog-

nize. The one is a failure of assimilation, and the other, no less important, is a failure of excretion. The skin is an important excretory organ, and it cannot be kept in the best functional condition without bathing. While we may not plunge a patient into a cold bath, we must see that he keeps the skin of the entire body cleanly, and as active as circumstances permit. Baths at a moderate temperature, when possible, or if not, daily sponging of the entire body should be insisted upon. This will often relieve pathological sweating. It is also a question of the greatest importance in how far we shall check sweating by drugs, whether, to reduce the skin to a dry and hot condition, is not far more dangerous than the very moderate perspiration for which atropia and other drugs are frequently given. This question must, of course, be decided in every case upon its own merits, with due attention to all the circumstances. Still I feel that it is often better to depend upon our general measures for the relief of this and other special symptoms than to resort at once to symptomatic medication.

Dr. M. Price said: I would ask Dr. Flick with reference to his experience with inflammatory conditions as a cause of phthisis. I do not believe in hereditary consumption. I believe that ninety per cent. of the cases of consumption come from some inflammatory condition as the starting-point. I am a firm and positive believer in the inflammatory origin of consumption. In nineteen years of practice I have not seen more than three or four cases in which I could not discover an inflammatory cause. I believe that without this inflammatory starting-point, consumption is impossible.

Dr. Flick said: I felt considerable hesitation in presenting this paper, as I knew that the opinions expressed were in conflict with those of many on the subject. I have strong convictions on the subject, however, as I have myself been the unfortunate victim of the disease. I have given the matter a great deal of thought, and have observed the effect of many remedies and of hygienic conditions. I do not know that those who have discussed the paper got my exact ideas on the subject. I hold that consumption is entirely dependent for its initial starting-point on malnutrition. I hold that without malnutrition and malassimilation such a thing as consumption cannot take place. I think that when one is run down he is then a fit subject for the bacillus tuberculosis, and unless he is run down and his digestive apparatus is out of order he will never fall a victim to phthisis, no matter of what his parents or his grandparents died.

The objection based upon the fact that nurses in hospitals do not contract the disease from their patients, is not well grounded. The nurses and others connected with a hospital are generally well nourished, as they get everything that is necessary to keep up their condition. When they get below par they fall victims to the disease. I believe that no consumptive patient derives benefit from climate in itself. The benefit comes from the change of life and from the out-of-door life. If the patient lives an out-of-door life and takes nourishing food he may recover. If he goes to any climate and stays in the house he will die.

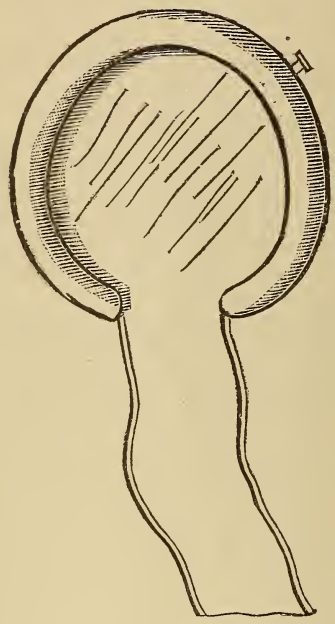
With regard to the relative frequency of the disease in males and in females, I would state that my statistics are drawn from the census reports of the United States. I have no doubt that inflammatory conditions of the lungs have some bearing on the production of the disease, inasmuch as a person who has had pneumonia is left in a depressed condition. I think, however, that a mistake in diagnosis is often made. I believe that a case is often considered to be one of pneumonia when really it is a case of phthisis. It is said that pneumonia has run into phthisis when in reality it was a case of phthisis from the beginning. I have brought this subject forward with the hope of exciting discussion. This is a matter which is too much neglected. There is no disease that causes as many deaths as does consumption, yet we have become so accustomed to it that we do not give it the attention which it deserves.

Dr. Howard A. Kelly read a paper on

Rubber Cushions for Surgical Purposes.

It is now almost a year since I put in the hands of Mr. Levick, manufacturer of rubber goods, several designs of cushions for surgical purposes. These cushions resemble those commonly used by students at lectures, in having an inflatable rim, but differ in being left open on one side, being C-shaped or rectangular, with one side out. They have a bottom of rubber sheeting extended into an apron some inches in length for the purpose of drainage. I have had constructed three separate forms, a large C-shaped cushion measuring about twenty inches in diameter, the opening of the C being about eight inches across, and the apron twenty inches in length. The rim measures about two inches in diameter when inflated. This pad I constantly use for abdominal sections; it is also of great

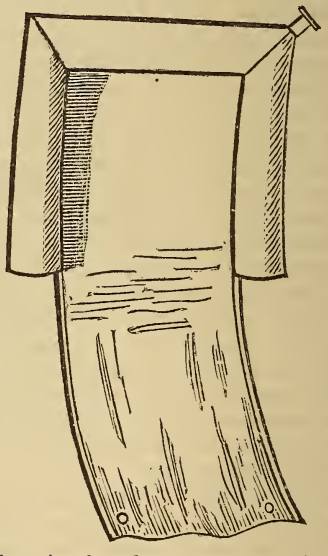
service in obstetrical cases requiring operative manipulation. It permits the free use of water for douching purposes; drains all blood and water from the field, enabling the operator to return the patient at once to bed,



without the necessity of removing clothing or changing linen. It has each month saved me more than its cost in the wash at my private hospital. A similar pad of the same pattern, measuring but ten inches in diameter, is in use on the examining table in my office, in all cases in which it is necessary to douch out the uterus or vagina.

The third pattern, which is in constant use for minor gynæcological work, is the perineal cushion. It is rectangular in shape, opening on one side, having a rubber bottom and long apron similar to the preceding. When in use the patient's clothes are elevated, and the thighs held flexed on the abdomen by my "Beinhalter." The buttocks are drawn down over the edge of the inflated rim, and the apron which hangs down from the edge of the table carries off all blood and the water used throughout the operation. There is no one device in all my gynæcological work which has given me so much comfort as these simple cushions. I use gallons of water with the utmost freedom, and without ever being obliged to think once where it is going. In perineal work, instead of using sponges, I use constant irrigation, which prevents clotting of blood, soiling of instruments, and replaces at no expense, and with greater comfort and satisfaction, the sponges formerly used. The work thus accomplished is neater and cleaner, and the results are better.

I also present now for the first time a design for a rubber bed-pan. It is oblong in shape with an inflatable rim and a rubber bottom. It differs, however, from any previous device, in the fact that one end communicates with a large, funnel-shaped reservoir, terminating in a large nozzle through which the fluids are finally discharged. The whole peculiarity of the device depends upon the funnel and its outlet; the funnel is very broad at the top, being the full width of the cushion, about seven inches in depth to the tube, terminating in the discharge pipe of the same length, which is perforated at its under side by a buttonhole for attachment, when in use, to the rim of the cushion. When the cushion is in use the rim is inflated, the discharge pipe is buttoned to the rim, and



the patient is placed upon the cushion. Vaginal or rectal injections are now to be given. The fluid, as it is discharged from vagina or rectum, accumulates on the floor of the cushion, the amount this will hold depending entirely upon the depth of the inflated rim and the size of the cushion and reservoir. When it is desired to empty it, the rim is caught in the hand at the upper end, and carried with the funnel hanging downward; all fluids at once gravitate into this, but do not escape, owing to the attachment of the discharge pipe to the rim. It is then carried to the closet and the discharge pipe unbuttoned, when the fluid rushes out; it is further cleaned by allowing the water to run freely through it in the same manner.

The advantages gained by this device are very great. The softness of the rubber is a great advantage over the hard bed-pan, the capacity of the cushion is much greater, and may be made to vary with the size of the reservoir alone. It can thus be used for purposes for which the bed pan is entirely inapplicable. The facilities for cleansing are perfect, eliminating the chief objection to which the rubber cushions hitherto in use are open. The ease of transportation is also an available feature, as when collapsed it can be rolled up and packed away in small space. It can also be used for continuous irrigation, by leaving the discharge pipe, which can be made of any length, hanging over the side of the bed, discharging on a piece of rubber sheeting which conducts the fluid into a bucket.

Dr. J. Price said: The only matter about which any question exists, the only thing in controversy, is whether Dr. H. A. Kelly has any claim whatever as the inventor or originator of the irrigation pad. Such claim he has not only set up here but elsewhere, without, I assert, a shadow of authority in fact. Introducing the instrument here he has made it legitimate matter for discussion, not only as to the merits of the instrument, but the genuineness of its authorship. About five years ago I conceived the importance of an irrigation pad or cushion, and from a design of my own my friend, Dr. John Madison Taylor, made a drawing. The instrument, as drawn, was ordered through Kolbe. Dr. H. A. Kelly saw it not only at the instrument store, but also at my office. He there examined it, and we discussed its merits. I here present a bill from the New York Rubber Company for making this operating cushion, dated January 7, 1885.

Dr. Kelly said: I am sorry that anything so unpleasant should have come before the Society, and I should not have brought up the matter had not the remarks in reference to it been made so publicly after the last meeting that I have been forced to defend myself. I can only repeat that I have no recollection that Dr. Price ever spoke to me on this subject.

—A thoroughly equipped children's ward has been added to the Presbyterian Hospital, West Philadelphia, through the liberality of one well-known lady, and the new ward was opened on January 31. It is hoped to interest others in its support, the funds of the hospital being required for the maintenance of the sixty free beds in the general hospital. Five thousand dollars is required to endow a bed in perpetuity.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 19, 1888.

The President, A. Jacobi, M.D., in the chair.

A Method of Prophylaxis in Diphtheria.

Dr. August Caille read a paper upon the Prophylaxis of Diphtheria, in which he said that every physician of experience had probably noticed that in certain families one or more members regularly become sick with diphtheria in the spring or fall of the year. It had occurred to him that the persons thus afflicted might harbor the microbes or essentials to the development of the disease from one attack to the other in the nasal and oral cavities. To test the correctness of this opinion of auto-infection, he chose eight children, who had prior to 1885 suffered from two or more attacks of diphtheria, and instructed their parents to carry out the following directions: First, all carious teeth were to be filled or extracted, and to be examined by a dentist from time to time; second, the mouth was to be rinsed three times a day after meals with one of three solutions, namely: a three per cent. solution of chlorate of potassium in water; a five per cent. solution of liquor sodæ chlorinatæ in water; or a saturated solution of borax in water. Some of the liquid was to be drawn up the nose. These instructions were carried out faithfully, and during two years, from 1885 to 1887, none of the persons experimented upon contracted diphtheria, although some of them had light attacks of pharyngitis and amygdalitis. In the family of three, the mother and nurse had diphtheria, but the children escaped. This form of prophylaxis, he said, had received scarcely any mention in medical literature. Inasmuch as we were ignorant of the true nature of diphtheria, we could not claim ability to make a diagnosis, especially in the early stage, between this and other affections of the throat and mouth; hence the importance in all doubtful cases, and indeed of every case of disease of these cavities, of protective measures, consisting of cleansing and disinfection. Parents should examine the mouths of their children before they go to school in the morning, and when sore throat is prevalent the children should be kept at home, and the above measures carried out.

The President mentioned as two possibilities in connection with diphtheritic infec-

tion, that the poison might rest in the enlarged lymphatic bodies or diseased mucous membrane in one who had suffered from an attack, and thus auto-infection take place. The slightest scratch might be the seat of erysipelatous inflammation; this he thought might also be true respecting diphtheria, particularly when the abrasion lay in the mucous membrane of the oral or nasal cavities. Those suffering from any acute affection of the mucous lining of those cavities are more liable to take diphtheria when exposed to it than others were. Another point of importance is the fact that children suffering from diphtheria often had relapses before complete convalesence, and this he considered due frequently to reinfection from the poison resting in the furniture of the room. Hence the importance of change of rooms, if not of dwellings, and of thorough airing, if not disinfection.

The discussion was participated in by Dr. Seibert, who emphasized the necessity for keeping the stomach in good condition if we would have children's mouths clean; by Dr. L. E. Holt, who had the impression that enlarged tonsils predisposed to diphtheria and made the attack worse, in which opinion the President agreed; by Dr. Winters, who, when diphtheria existed in a family, gave the well children full doses of tincture of chloride of iron, quinine in tonic doses, and calomel in mild purgative doses; and by Dr. Fruitknight and Dr. Harrison.

Dr. T. R. Pooley then read a paper on

The Induction of Premature Labor in Amaurosis and Amblyopia in Albuminuria from Pregnancy.

Among the indications for abortion in the albuminuria of pregnancy, disturbance of vision had not received the attention which its importance should demand. It had long been known that pregnant women were liable to disturbance of vision, but its importance had not been realized until written upon by Dr. Loring, who was first to suggest the induction of premature labor to save vision. It was true that in the case related by Dr. Loring it could not be shown by other symptoms that the kidneys were affected, but the value of his suggestions held good in this class of cases. The disturbance of vision connected with the albuminuria of pregnancy did not usually become prominent before the last months, and often grew worse for a time after pregnancy ceased; yet the lesion in the eye might begin at an early period after conception, as was evident in some cases in which an ophthalmoscopic examination was made. The disturbance of vision might come on suddenly or gradually; it might be transitory or permanent; it might be slight or extend to complete loss of vision. The author related one case in his own practice, and several others in the practice of different physicians, in some of which spontaneous abortion took place with immediate marked improvement in vision. In others pregnancy was allowed to go on to full term. In others premature labor was induced, with improvement in the eye symptoms. He thought nature had given us a valuable lesson when in some cases she brought on spontaneous abortion, after which the ocular difficulty improved. He believed an ophthalmoscopic examination should be made regularly in all cases of pregnancy, just as we now examine the urine for albumin.

Dr. Loring agreed with the author regarding the necessity for ophthalmoscopic examinations early in pregnancy. He spoke also of optic difficulties connected with other disturbances of the uterus than those related to pregnancy, but which in one case had nothing to do with nephritis.

Dr. Murray had frequently made examinations of the eye with the ophthalmoscope during pregnancy, and, according to English observers, as quoted by Dr. Loring, the lesions referred to by the author of the paper as occurring in the albuminuria of pregnancy were present in more or less degree in a large percentage of the cases. Yet few women who had albuminuria had eclampsia, and few of these again had serious optic difficulties. Therefore such examinations, if generally practiced, would only give the physician and patient unnecessary anxiety.

After some further discussion the academy adjourned.

—Diphtheria and typhoid fever are prevailing to an alarming extent in the neighborhood of Ottawa, Canada. Every town and village has been visited by either one or both of the epidemics, and the death-rate during December, 1887, from these causes was unprecedented. Twenty per cent. of the deaths in Montreal in one week recently were from diphtheria. In Ottawa, typhoid fever appears to be the most prevalent. The hospitals are full to overflowing, and can take in no more patients. A commission has been appointed to hold an investigation. The water supplied to the city is being drawn from the vicinity of a creek into which all the refuse of a tannery is emptied, and which an analysis shows is terribly polluted.

Reports of Clinics.

ROOSEVELT HOSPITAL, NEW YORK.

SURGICAL CLINIC—PROF. SANDS.

Ellstädter's Operation.

On January 7, 1888, Professor Sands presented a patient at his clinic who came under his care under peculiar circumstances. Not long since he had received a letter purporting to come from a country physician, who asked Dr. Sands whether the latter thought a cure possible in a case of fistula of the chest following by a pleurisy, which had then existed several years. The correspondent stated that if Dr. Sands considered the disease curable, the patient would be sent to him. The writer at the same time begged for information generally regarding the affection, and asked to be referred to some work treating of the subject. In reply, Dr. Sands informed the supposed doctor that the affection was curable, and that by means of Ellstädter's operation, and referred him to the *Archiv für Chirurgie* for further information. Some time thereafter a man called at Dr. Sands' office and introduced himself as his correspondent. It was subsequently learned that he was not a physician at all, but was himself the patient. He is thirty years of age, and single, and was admitted to the hospital on January 5, 1888. He says that he never was a strong man. Five years ago he had some brain trouble and an attack of pleurisy, with effusion. The fluid was aspirated four or five times, and, according to the patient's account, a gallon removed. In December of the same year (1883), an incision was made in the sixth intercostal space, and a drainage-tube introduced; but the fistula never healed. The breathing on the left side at present is found to be good; on the right, poor. His chest, upon the right side, is sunken and hollowed out from side to side. Dr. Sands thought that aspirations in cases of purulent exudations were of no use, in fact injurious; and that such exudations should be looked upon and treated as abscesses, that is, by incision. He objects to two openings being made, one, in his opinion, being sufficient; and does not believe in excising ribs, unless it really becomes necessary. "In the present instance the case is different; this patient has already two openings, and the chest, being flattened, the lung could not expand, because the lung is bound down by adhesions and would not resume its volume, even after a cure had been effected." On being tested, the cavity of the sinus was found to hold a gill, and to extend upwards for about four inches; laterally and inferiorly to a much less distance. An incision having been made in the side of the chest, the skin flags turned back, and the periosteum loosened from the ribs, a considerable portion of ribs was excised, and the soft tissue, consisting of thickened pleura, was then cut out by a curved incision. The wound was then probed. Dr. Sands was surprised to find that the sinus ran upwards for eight inches; and, greatly disappointed in his expectations, he decided not to excise any more ribs unnecessarily, as he now doubted of the cure he had promised this patient, but consoled himself with the knowledge that he would at least obtain good drainage. Two drainage tubes were then introduced, two being used so as not to exert too much pressure in the first place, and in the second, in order that the cavity might be washed out more readily, if necessary. The wound was then sutured and dressed in the usual way.

Stricture of the Urethra.

The second case presented to the class by Dr. Sands was one of stricture of the urethra. The patient was 42 years of age, had had gonorrhœa three or four times before he reached his twenty-eighth year, but no attack since then. From the last attack he did not fully recover, having had a "running" ever since. The stream of urine which he is able to pass has become smaller and smaller, and he has now to pass his water every two hours at night. A prior examination revealed the fact that he had many strictures. The attempts to pass the larger and then the smaller sized sounds being unsuccessful, a filiform bougie was introduced. The Maisonneuve urethrotome thus guided, first a small-sized and then a large-sized knife was used to cut through the strictures. A few of these were present in the penile portion, and several in the course of the canal, among which was a very resisting one at about the junction of the membranous with the spongy portion of the urethra. The introduction of a No. 20 catheter and the drawing off of the urine was the final step. Prof. Sands is in the habit of leaving these cases severely alone for seven or eight days before beginning dilatation.

—The reports concerning the condition of the Crown Prince of Germany continue to be encouraging.

Hospital Notes.

Bellevue Hospital, New York.

(Service of Prof. F. S. Dennis.)

For the following reports we are indebted to Dr. Thomas McCann, House-Surgeon.

Contusion of the Eye.

P. H., 25 years old, and a laborer by occupation, was admitted to Bellevue Hospital on August 28, 1887. While at work on the afternoon of August 27, a piece of steel or stone struck the patient's left eye. The following condition of things was found on his admission twenty-four hours later: The eye was greatly inflamed, the cornea sloughing, and eye-ball protruding. Leeches were applied and cold compresses used. On August 30, hot applications were substituted for the cold, and a canthoplasty advised and executed. The eye immediately bulged through between the lids and became constricted. Cold and hot applications were alternately applied, and atropine drops, which had been used every three hours since the patient's admittance, were continued. A panophthalmitis resulted. The eye was left to discharge. On September 5, the eye was discharging freely; there was no pain in the right eye. On September 10 the eye was still discharging, but the inflammation was subsiding. By September 20 the discharge had ceased. The patient was discharged cured on October 3.

Dislocation of Knee.

T. L., 64 years old, was admitted on September 12, 1887, having injured himself by falling down a cellar-way. Upon his admittance there was found a backward dislocation of the knee, which, being reduced, an existing fracture of the internal condyle of the femur was also discovered. A peculiar pinching of the skin at the side of the knee-joint was taken notice of, appearing as though the integument had been caught between the head of the tibia and the inner condyle; but this, upon close questioning, was found to be due to an old cicatrix, which gave rise to this appearance. Continuation of cold applications was advised. On September 19, the limb had improved considerably, but still presented a great amount of redness about the inner condyle. On manipulation, attention was called to the great outward mobility of the leg, and a closer examination revealed a rupture of the internal lateral ligament. On September 25, the limb had been on a double inclined plane for some time; a lead and opium lotion was applied; the limb was gradually improving. On October 6, a posterior splint was applied, and the patient allowed to get up. He was dismissed on October 13.

Sarcoma of Neck.

L. M., 62 years old, married, a native of the United States, was admitted to the hospital August 15, 1887, with a large growth on the left side of the neck. The patient said that a similiar but smaller growth had been removed eight weeks previously. On September 22, the growth being cut down upon, was seen to involve the sternal end of the clavicle, and as much as possible of it was removed. The bifurcation of the innominate artery was plainly seen and felt in the course of the operation. On September 24, the wound was dressed, and was looking well. Five days later the wound had broken open, and was filled with granulations. On October 1, the surface of granulations was found to be larger and spherical in shape, evidently malignant. By October 12, the new growth had become fully as large as before, and evidences of pressure upon the trachea began to appear. On October 19, the growth was much larger than any of the previous ones, and showed a large surface of granulations. It was not deemed advisable to remove the tumor, and the patient was discharged on October 30.

Neuroma.

S. St. J., 53 years old, a native of the United States, was admitted on October 3, 1887. The patient said that he had had an amputation performed at the shoulder-joint, twenty-nine years ago, for an injury to the arm; and further that this region has been more or less painful for the last fifteen years. On manipulation a small deep-seated and very sensitive tumor was felt. The tumor was cut down upon and excised on October 4, and was found to be a neuroma of one of the cords of the brachial plexus. The wound was drained and dressed in the usual way. On October 7, the wound was dressed and the tube removed; the wound looked well. On October 12, the wound was dressed; it looked slightly angry. The patient was discharged cured on October 19.

Necrosis of Humerus and Tibia.

T. B., twenty-eight years old, a native of the U. S., was admitted on October 10, 1887. His trouble began last February, when he was first taken with rheumatism, and subsequently noticed a swelling of his left leg. This had been lanced, giving exit to a "dark matter." Some two months thereafter he

noticed a swelling of the right arm. The swelling of the right arm was cut down upon, on October 11, and a necrosis of the humerus was discovered. The bone was gouged out, scraped, and the wound packed with iodoform gauze, and dressed. The tibia was next cut down upon, and an extensive necrosis of that bone found. This was chiselled, and a piece about three-quarters of an inch wide by two inches long cut out, the centre of which was necrosed. This cavity was also scraped out, and the wound plugged as above. On October 14, the patient was doing nicely. By October 21, the wound in the arm had almost filled up. On October 22, the wound of the leg was found to be doing very well. Sponge-grafts were introduced into the leg on November 1.

Supra-Pubic Lithotomy.

P. R., aged eight, was admitted September 23, 1887, with a history of calculus of the bladder. He was sounded, and the stone being detected, supra pubic lithotomy was performed. The bladder having been injected, an incision was then made in the median line, in the usual way. A catheter being introduced, the peritoneum was then pushed back, the areolar tissue separated, and an incision next made down upon the catheter into the bladder. This incision into the bladder being enlarged, the stone, the size of a hazelnut, was then easily removed. A drainage-tube was next introduced into the bladder, and the wound allowed to heal by granulation. The abdominal wall was stitched up and around the drainage-tube, and the wound dressed antiseptically. On September 27, the boy's condition was fair; he showed slight evidences of peritonitis for the first three days. On October 6, the wound having separated, was filling with granulations, having a surface two inches square. The boy's condition was otherwise good. By October 13, the granulation surface was gradually decreasing. On October 21, the patient passed water by his urethra. On October 29, the patient developed an abscess on the left side of the neck, which was due to a decayed tooth. On October 31, the abscess was incised. The temperature had gone up to 104.8° F. November 2, the wound of the neck had healed. A hair-lip pin was then introduced into the vesical fistula, and the edges of the granulating wound brought together. November 5, the pin was found of no benefit, as the patient still passed urine from the abdominal wound. By November 10, the wound had entirely healed, and the patient was walking about.

Periscope.

Therapeutics of Diphtheria.

In a paper in the *Medical Record*, Dec. 24, 1887, upon the therapeutics of diphtheria, with especial reference to the oil of turpentine, Dr. Simon Baruch, who has had great experience with this disease as attending physician to the New York Juvenile Asylum and the Manhattan Hospital, says that disinfection of the throat is best accomplished by the frequent internal administration of tonic, astringent and antiparasitic remedies; not by the brush, probang, or atomizer. Neither water nor food should be permitted for ten minutes after the medicine has been swallowed, thus allowing it to bathe the diseased surfaces. When the patient is tractable and willing to aid the attendant, he advises the hourly application of a fifteen per cent. solution of tripsin. In one case a ten per cent. papayotin solution proved equal to tripsin, but much more expensive. In *nasal* diphtheria the tripsin solution is invariably prescribed, to be applied hourly with the medicine dropper or soft brush, because this can be accomplished without damaging the mucous membrane, even in an intractable child. It softens and pulpifies the false membrane, and facilitates its removal by injections of salt water, or 1 to 10,000 bichloride, which in this dangerous form he orders applied at frequent intervals. When the air-passages are involved, he also resorts to local treatment by inhalation of the vapor from boiling lime-water impregnated with oil of turpentine—one ounce of the latter to one quart of the former, used continuously. When properly applied, he says these inhalations have aided him in saving several of his patients from tracheotomy. Great care should be taken not to deprive the patient of an ample supply of pure air while the inhaling apparatus is in operation. It is a common practice, which he admits formerly practicing himself, to surround the patient by all possible safeguards against the escape of the medicated vapor. A tent is usually constructed around the couch, excluding to a great extent the air, and compelling the patient to inhale the vapor continuously in its fullest concentration. This is an irrational practice. A patient suffering from laryngeal stenosis requires a plentiful supply of oxygen. Hence it is of vital importance to enforce at least as free access of fresh air to the chamber in laryngeal as in the other forms of diphtheria. It is only necessary to direct the vapor by means of a tube to the immediate vicinity of the

patient's mouth. This application requires constant and unremitting care. In this, as as in every other detail in the treatment of diphtheria, vigilance is the price of success; the physician must himself devote time to instructing the nurse again and again. The nurse should be warned against admitting cold air currents to reach the patient. As the latter is usually more or less somnolent in laryngeal diphtheria, it is not difficult to execute the necessary steps.

As to the general management of the patient and his surroundings, it is universally admitted that cleanliness of body, quietude of mind, and gentleness in nursing are among the chief elements of successful treatment. One point, however, he thinks deserves mention. In severe cases, especially if protracted, a change of rooms produces a marked effect. A fresh room, which has been thoroughly ventilated for twenty-four hours; a fresh bed, supplied with clean, well-aired linen, mattresses and blankets, and new surroundings, will effect a marvellous change in some protracted cases of diphtheria.

The administration of easily digested broth, milk, and stimulants must be left to the indications of each case. Care should be taken, however, to limit the quantity of food in proportion to the digestive powers of the patient. There exists in this disease, as in typhoid fever, a tendency to overfeeding.

As to internal medication he says his practice is to give every case of diphtheria, not presenting diarrhœal symptoms, a full dose of calomel, from four to eight grains, according to age. This is followed in six hours, if necessary, by a saline laxative in the mild tonsillar cases, while in the more severe types the action of the calomel is aided by ʒj to ℥ss of oil of turpentine. The latter usually produces several pultaceous stools. The gastro-intestinal tract is now prepared for the reception of food and the necessary medication; the temperature is usually reduced, and the patient's comfort enhanced. Hitherto these were the chief objects of the calomel treatment. We have now, he thinks, another reason for its value, in the fact that calomel in purgative doses has been successfully used to abort other infectious diseases, as has been demonstrated by Ebstein and others.

Tincture of the chloride of iron is another remedy which he prescribes in all cases of diphtheria, but he gives it in doses from eight to twenty-five drops every hour, only sufficient glycerine and water being added to somewhat soften its astringent taste; the more concentrated the better the local effect. It is administered two hours after the calomel, and continued hourly or bi-hourly night and day. He lays stress only upon one point, unimportant as it may seem; *food or stimulants may precede the iron, but should never follow it immediately.* Then a local effect is obtained, which is readily recognized in the shrivelling of the deposit and the reduction of the circumjacent lividity. Bichloride of mercury is prescribed in all severe cases, especially when the uvula, nose, or larynx are involved. He administers oil of turpentine in doses of one drachm to half an ounce to children from six to fourteen years of age, once a day, oftener in cases demanding it. It may be given pure, followed by milk, or mixed with milk, or in emulsion. Vomiting occurs sometimes after the first dose, but the drug is usually retained afterwards. On two occasions his hospital nurse, alarmed by the rapid spread of the deposit, administered an ounce to children of twelve and fourteen years of age, with good effect. In about fifty per cent. of the cases it produces a laxative effect; it always stimulates the secretions of kidneys and skin; the odor is quickly detected in these as well as in the fæces.

He calls attention to the advantage of administering remedies in such form and rotation as to obtain their local antiseptic effect in connection with their general effect, and states that the entire number of cases treated by the method above indicated was thirty-nine—thirty being in hospital, nine in private practice. Mild and doubtful cases were rigidly excluded from this record. Among these thirty-nine cases there were two deaths, both in hospital practice; one occurred in sixty hours, and the other in fifteen days. In the first fatal case swallowing was so difficult that medication was not properly executed; in the second case the deposit disappeared so rapidly in three days that turpentine and bichloride were discontinued. Gastric irritability appeared several days later, when iron also was suspended. The patient died from neuritis.

Contributions to the Surgery of the Lungs.

Zielewicz reports the case of a boy, fifteen years old, who had been affected with a pneumonia, secondary to an attack of measles. Three months later, in examining the patient, he established the existence of an encysted pleural effusion, containing pus. He resected the sixth and seventh ribs to give vent to the pus. After having washed out the cavity he examined it by reflected light, and discovered on the surface of the lung a small orifice of the size of a pea, from which ichorous

pus escaped. With the aid of a long bistoury he enlarged this opening and then introduced his little finger into it. The cavity was thus found to be large enough to hold a walnut, and occupying the lower lobe of the left lung. The opening was tamponed with strips of iodoformed gauze, the ends of which were free and were brought out of the thoracic cavity. The cavity of the empyema was also tamponed in the same way. Then a dressing of chloride of sodium and sublimate gauze, with a layer of cotton, was applied. Cure resulted in eight weeks.

In another case, the patient was a man thirty years old, who had empyema, for which the thorax had been opened. Three weeks later, the opening which had been made contracted to such a degree that drainage no longer occurred, and fever resulted from the retained pus. Zielewicz then resected the seventh rib, washed out the pleural cavity and explored the surface of the lung with his finger. He happened upon a depression which, examined under sufficient light, had all the appearances of the residue of an abscess of the lung on the way to recovery, and of having been the point of departure for the empyema. Six weeks later, the patient had completely recovered. The author adds that he has not devoted himself to deciding whether the abscess was complicated with gangrene or not, as all the facts of the case place it in the category of those in which recovery from empyema occurred through surgical intervention. —*Gazette Médicale*, December 10, 1887.

Cocaine in the Treatment of Diseases of the Skin.

S. Lustgarten reports to the *Wiener med. Wochenschrift* that in Prof. Kaposi's clinic for skin diseases, painting with a two per cent. solution of cocaine has been found effective in diminishing the itching of acute and subacute eczemas. In eczemas of the genitalia and of the buttock, a two to five per cent. ointment of cocaine in lanolin proved itself particularly useful. In pruritus ani, suppositories, each containing three-fourths grain of oleate of cocaine, are employed in addition. It has also been used for the following purposes: in a one per cent. ointment for painful abrasions of any kind; in two per cent. watery solution to paint upon granulations which are to be touched with nitrate of silver; and also as an injection into the urethra in painful erections, chordee, etc., in the course of gonorrhœa. It has also been used with a two per cent. solution of carbolic acid, in the form of hypodermic injections, in order to produce local anæsthesia for minor operations, such as extirpation of epitheliomas, circumcision, and the like. In the same way it suffices for making painless hypodermic injections of calomel, for which purpose the needle of the instrument should be allowed to remain in the tissue while the barrel is removed to be filled with the calomel mixture. Arsenic injections can be made in the same way. If these substances were added directly to the cocaine solution, decomposition would occur. Daily use of cocaine in calomel injections the author regards as inadvisable, on account of the danger of inducing toxic effects. In some few cases the author observed palpitation of the heart, and general indisposition, tremor of all the extremities, and once even an epileptiform attack, from the hypodermic use of three-fourths of a grain of cocaine.

Scrofulous Neck and its Surgical Treatment.

Dr. William F. Gibb, in a paper published in the *Glasgow Medical Journal*, January, 1888, after discussing scrofulous neck and the remedies proposed for its relief, states his opinions in the following propositions:

1. In scrofulous disease of cervical glands we have a tubercular process of a mild type, seldom leading to generalized infection, but perhaps occasionally doing so; frequently concerned in predisposing to, or even directly occasioning, phthisis pulmonalis; and in the majority of cases deteriorating the general health.

2. Tubercular disease of the cervical glands is too often allowed to go on to a disastrous extent, without any active steps being taken to arrest its course, largely from a prevalent indifferent and helpless feeling on the part of the medical profession.

3. Slight cases, being of course offered every possible advantage in the matter of constitutional treatment, should be carefully watched; and if, after the lapse of months, or it may be a year or two, we find the disease spreading, it is wise to extirpate the affected glands while they are yet movable. In such cases the operation will be easy, and little or no deformity need result.

4. To quote Teale, whose directions are full and clear, surgical interference is demanded whenever a sinus resulting from a degenerating gland exists; whenever pus can be detected in connection with a gland; and whenever there are enlarged glands accessible to surgery in a patient in whom a caseous or suppurating gland has already been discovered.

The author appends to his paper four cases illustrative of the disease and its treatment.

The Usefulness of the Trichloride of Iodine as an Antiseptic.

C. Langenbuch, of Berlin, communicates to the *Berliner klin. Wochenschrift*, No. 40, 1887, a paper upon the usefulness of trichloride of iodine as a disinfectant and antiseptic. He finds that it does the work, in abdominal surgery, of a four per cent. solution of carbolic acid, or of a five-hundredth of one per cent. to one-tenth of one per cent. solution of bichloride. Riegel has declared that there is no fear of poisoning from its use in surgical practice; but, in spite of this assertion, Langenbuch states that he always employs it cautiously, especially at the beginning. The following are his conclusions with regard to the antiseptic power of the trichloride, which we take from the *Allgemeine med. Central-Zeitung*, Dec. 7, 1887:

1. In watery solution, the trichloride is an active disinfectant, being capable of killing vigorous spores of bacilli, even when it is in great dilution (1–1000). Solutions in oil and alcohol are inactive. Its spore-killing power surpasses by far that of carbolic acid, and, in this respect, among the ordinary disinfectants, stands next to the bichloride.

2. In its behavior toward bacilli free of spores, and toward cocci, it exhibits about the same activity, in a solution of one to one thousand, as a carbolic acid solution of three in one hundred. In greater dilution it in some experiments appeared to exceed carbolic acid in power.

3. The antiseptic properties of the trichloride are effectual in preventing the development of the micro-organisms of infectious wounds, if it is added to the nutritive gelatine in the proportion of one in two hundred.

The author concludes his paper by saying that he has used the trichloride in all kinds of major operations, and has obtained throughout successful results. In abdominal operations its value seemed particularly striking, as it was disinfectant without giving rise to any toxic symptoms. He has also used it internally in solutions of one part in 1200 to 1500 in dyspepsia with fermentation, and also as an injection in gonorrhœa.

Amylene Hydrate as a Hypnotic.

In the *Deutsche med. Wochenschrift*, January 5, 1888, George Avellis reports the result of experimentation with this new hypnotic in Riegel's clinic, at Giessen. The following propositions cover the results obtained in over three hundred trials with over forty patients: 1. Amylene hydrate can be depended upon as a hypnotic, if a sufficient dose is given. Control experiments have resulted in showing that it is weaker in this respect than chloral, but stronger than paraldehyde. 2. It also acts upon people who are accustomed to narcotics; yet for such patients a large dose (sixty grains) is required. 3. Sleep occurs for the most part quickly, without a preceding stage of excitement. The sleep is more or less sound in proportion to the size of the dose, but it is always possible to easily waken the patient. On being waked, the patients are completely clear in mind, answer questions correctly, and, if not further disturbed at once drop off to sleep again. 4. Sleep lasts, when small doses are given, two or three hours; when larger doses (thirty to thirty-six grains) are given, six to eight hours. 5. The awaking resembles entirely that of the natural sleep, and the patients feel strengthened. 6. The respiration is unaltered. 7. The change of pulse and blood pressure, apart from the slight slowing in the pulse rate which is to be observed even in normal sleep, does not occur after the administration of amylene hydrate, as is shown by sphygmographic tracings, which were taken by Prof. Riegel from different patients. 8. The bad taste and smell on awakening, which often after the use of paraldehyde annoys the patient and those about him, has never been observed from amylene hydrate. 9. Whether patients become accustomed to the drug, or not, can not yet be decided. In the author's experiments it was never necessary to increase the dose after it had been employed repeatedly for some time. In one patient, a hysterical woman, who had taken thirty-six grains of amylene hydrate, a condition of intoxication developed. The skin of her face was reddened, the pulse quickened; she was talkative, and stated that she was as though intoxicated. After the lapse of four hours, sleep occurred. Another patient took thirty-six grains at one o'clock in the morning, and on the next day felt as though he had been under the influence of a hypnotic. Probably the late hour at which the drug was taken was to blame in this case. The drug failed in three cases: one of these was a patient with delirium during erysipelas, one a patient with beginning insanity, and one a patient suffering from very violent neuralgia. In the irritative cough of phthisis, the cough was not increased, but rather diminished.

When the drug cannot be administered by the mouth, as in severe disease of the stomach, or ulcerous processes in the pharynx, it may be given with water and gum Arabic in the form of an enema.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

MASTURBATION IN WOMEN AND GIRLS.

The vice of masturbation is far from being limited to the male sex. The ancients designated female masturbators as *tribades*[1] (*tribein* to rub), and the Lesbian women from the time of Sappho, that ancient erotic woman, had the reputation of solitary sacrifice to Venus. There is evidence that phalli of wax or of wood were offered publicly for sale among the Romans, as now among the Chinese. That the odious practice has come down to modern times is also evident enough, and more than one romance of our day has called attention to the prevalence of the solitary vice (tribadism) among women.[2] Instances of each of the three following forms of masturbation frequently come under the notice of the physician: vaginal, clitoridian, urethral. Of these three forms, the clitoridian (simple titillation or friction of the clitoris by the hand), is the most common. Peculiar movements of the body, often calculated for this end, may accomplish the same titillation of the clitoris ending in voluptuous spasm. In one large tailoring establishment Pouillet found a number of girls who had become addicted to masturbation by the use of the sewing machine; they had learned the habit of sitting in such a posture that the motion of the feet on the treadle brought about a pleasurable friction of the clitoris by the thighs.[1] A confirmed female masturbator will practice the vice by rubbing the genitals against the arm of a chair, the corner of a piece of furniture, or even by divers contortions of the body. Vaginal and urethral masturbation has sometimes resulted in the lodgment of foreign bodies in those passages, and the intervention of the surgeon to remove the foreign body has been necessary. Dupuytren in one instance extracted a *tin-cup* from the vagina of a confirmed masturbator;[2] and, in another, a needle-case, introduced into the urethra, was successfully removed, after being present in this canal for a month.[3] The list of substances used for the purpose indicated is varied: from spools, needle-cases, bottles, glass cups, etc., in the vagina, to needles, ear-picks, pieces of wood, and hair-pins in the urethra. Confirmed victims of secret vice have been known even to provoke titillation of the uterus by hair-pins, pieces of reed, etc., as in an instance recorded in the *Journal de Médecine et de Chir.*, vol. xiv, p. 70.

With reference to the female masturbator observers have not failed to remark the obstinacy with which the vicious practice is often adhered to, despite every possible means of repression. Girls often begin this secret habit at a very young age, taught (though not always) by lewd nurses or playmates; and the frequency and persistency with which the pollutions are repeated, notwithstanding all opposing moral agency and all physical restraint, is appalling. Nearly all physicians at some time or other have had experience of such cases.

As for the causes of this vice, when we think of the altogether disproportionate share which sensual and sexual gratifications have

[1] Martial, 7–67; Phædrus, 4, 15.

in the daily lives of multitudes, the intense pre-occupation of their minds with such matters and the interest taken therein—as is evidenced in the popularity and sale of certain recent French novels; moreover, when we consider the sure influence of heredity: "*Casta refert castæ genitricis filia mores; lascivæ nunquam filia casta fuit,*" we do not wonder at the numerous instances in which this unnaturally developed and predominant passion has overflowed the bounds of decency, morality and physiological sanity. Pouillet makes four principal orders of causes: (a) physical, (b) social, (c) intellectual and moral, (d) mixed. Among the physical causes, climate has a certain share: the salacity of the inhabitants of hot climates has been recognized from remote antiquity. Want of cleanliness is an important factor, provoking irritation of the genitalia by the acridity and irritation of retained secretions. The same irritation, provocative of frictions which end in habits of manustupration, may be caused by ascarides, vegetations at the entrance of the vagina, vaginitis simple or blennorrhagic, vulvitis—and especially that variety of vulvitis which is localized near the clitoris—pruritus of the vulva, certain affections of the skin and mucous membrane whether local or general, and certain inflammations of the uterus and ovaries. Highly seasoned foods and stimulating drinks may favor this vicious habit, and certain cases of inveterate onanism appear to have originated in cerebral disease. Numerous instances have been met with in which the abominable habit was a manifestation of an insane neurosis, idiocy, or dementia.

Among the social causes, an indolent, sedentary and luxurious life is doubtless influential. Every conceivable perversion of the sexual function prevails in the harems of the East. Lewd romances, lascivious pictures, examples which favor precocious or inordinate sexual development, may be reckoned among the intellectual or moral causes.[1]

In treating of the consequences of onanism, it may be remarked that these are essentially the same in both males and females. This vice entails just such functional incapacity and anæmia of the brain and spinal cord as do all the other sexual abuses. It is doubtless more the frequent repetition of the act, than anything else, which renders masturbation so deleterious. The miserable victim steadily loses will power, and suffers deterioration of the higher faculties; and eventually the unnatural passion becomes dominant. Doubtless women, in consequence of the greater delicacy of their nervous organization, are the greatest sufferers from the effects of this vice.

Making all due allowance for exaggeration, and for mistakes arising from simple concomitance, there is evidence that, besides neurasthenia, nearly all functional nervous diseases may have their origin in self-pollution; this remark is true of both sexes. Putzel reports a case of epilepsy in a female aged nineteen years, which was clearly traceable to an inveterate habit of masturbating, commencing at the age of nine years.[1] Tissot, in his treatise on onanism, alludes to the frequency of epilepsy in the female as a result of self-abuse, and the aggravation of the crisis by repetition of the pollution. More than one case of epilepsy has been benefitted, if not cured, by clitoridectomy.

There is an analogy between the venereal spasm and epilepsy which has given rise, among the older medical writers, to the application to the former of the term *epilepsia brevior*. There is some clinical evidence that that obscure and protean malady, hysteria, is often due to habits of masturbation (Jolly, Bridges, Tissot, Kiwisch, etc.); catalepsy, ecstasy and chorea have also been referred to this vice. Pouillet relates a case of a choreic patient under his care, who, after intervals of apparent reformation and health, would be again afflicted with chorea when she resorted to her old habits of masturbation.[2]

Whether or not the grosser encephalic and spinal lesions ever result directly from this vice, it may not be possible to assert posi-

[1] *Vide* Parvin, in *Medical and Surgical Reporter*, Dec. 24, 1887, p. 826.

[1] Functional Nervous Diseases, p. 53.
[2] Pouillet, *op. cit*, p. 152.

tively; at the same time there can be little doubt that a peculiar form of mental degradation and alienation, characterized by notable changes in the affective faculties and in the character, is frequently a consequence of self-abuse. The victims of the genesic vice are timid, sheepish, inordinately sensitive, irritable, capricious, impatient, selfish, unfeeling, incapable of lofty thoughts, noble actions or good sentiments. One marked characteristic of this class of patients is that they spend long periods without weariness in doing nothing, or in doing very trifling things. Maudsley says: "they are wrapped up in self; display a vanity and self-sufficiency quite unbecoming their age and position; exact the constant indulgence of others without the least thought of obligation or gratitude." "Perhaps," adds Maudsley, "it may be looked upon as a fitting retribution that the completed destruction of the moral sense should have its cause in the vicious abuse of that instinct in which it had its original root." [3]

SCARLET FEVER AND FOOT AND MOUTH DISEASE.

Among recent studies in regard to scarlet fever none is more interesting or more worthy of serious consideration than that of Dr. Stickler, of Orange, New Jersey, as described in a paper published in the New York *Medical Record*, December 10, 1887. In this paper, the author gives an admirable description of so-called foot and mouth disease as it manifests itself in man and in lower animals, especially of the equine and bovine species, and an interesting account of what he has learned, by reading and by personal observation and experiment, of its relation to scarlet fever. From this account it appears that accidental inoculation of human beings, with secretion from the lesions of animals suffering with foot and mouth disease, produces a disease so similar in its manifestation that it seems to be identical. A more remarkable result of his studies is the indication—we cannot say, and he does not say, proof—that a previous attack of scarlet fever protects against the development of the disease from the ingestion of milk from animals suffering with scarlatina. That this may be a fact appears to be proved by a careful study of the cases of epidemic sore throat occurring in Dover, England, in 1884, which were attributed to the use of milk from cows suffering with aphthous fever. We cannot go into the details which Dr. Stickler has obtained, with the co-operation of Dr. M. K. Robinson, medical officer of health of East Kent, England; but commend them to the attention of our readers.

Another deduction from Dr. Stickler's observations and experiments is the theory that designed inoculation with the virus of mild aphthous fever (foot and mouth disease) in cattle affords protection against the accidental production of scarlet fever by contagion. Impelled by his convictions in regard to the relation existing between these diseases—or, it may be, their identity—he has actually inoculated a considerable number of human beings with the virus of aphthous fever, and has afterwards deliberately exposed some of them to the risk of contracting scarlet fever, with every effort to make this risk as great as possible. The result has been fortunate for an experiment which most men would regard as extremely hazardous. None of the subjects of his experiments contracted scarlet fever! And no one can question the conclusion which he states, with every proper reserve, that such inoculation appears to have a prophylactic value analogous to that of Jennerian vaccination.

It is impossible as yet to state positively—and Dr. Stickler appreciates the fact fully—that inoculations with the virus of a mild aphthous fever will serve as a reasonably safe and sure protection against the accidental contraction of scarlet fever; but his studies and experiments are deserving of the most thoughtful consideration. Many of our readers may be in a position to throw light upon the relation of eruptive diseases among cattle to the appearance of scarlet fever among their patients, as we have already stated in the Reporter, Nov. 26, 1887; and we hope they will co-operate with him, and with investigators on the other side of the Atlantic, in eluci-

[3] Maudsley, Pathology of the Mind, 3d ed., p. 453.

dating this important feature of the natural history of scarlet fever. As to preventive inoculations, we think they may for the present be left to those whose faith is clear in regard to their value; but we may indulge the hope that what Dr. Stickler suggests as to their worth as a prophylactic may not prove an *ignis fatuus*. If it be established as a fact, it will be of incalculable benefit to humanity.

EASTON PHYSICIANS FIFTY YEARS AGO.

We have received a copy of the *Easton Daily Express*, January 16, 1888, containing a communication from Dr. Traill Green, in which he defends the Easton physicians of about the year 1830 from a charge contained in the autobiography of the late Dr. Gross, that at the period in question the medical profession of that town was in a decidedly mediocre condition, without science, without learning, without progress, and apparently without ambition.

Dr. Green naturally objects to such a criticism of his townsmen, and warmly enters the lists to show that Dr. Gross's judgment was a mistaken one. In this we think he is entirely successful, and we share the general regret that one who in his life seemed to take such pains to avoid wounding the self-love of his fellow-workers should now be authority for a statement which certainly could not be expected to please them. The physician of fifty years ago cannot be judged fairly by the standard of the present day, and we have no doubt that the physicians living in Easton at that time were as conscientious, as intelligent and as skillful as any similarly situated medical men. The criticism of Dr. Gross must, therefore, be regarded as one of those lapses to which all men are liable, and from which no autobiography is free; and we trust that now, when the reputation of the Easton physicians has been so fully and so ably vindicated, the feeling naturally excited by the injustice done them will disappear, and the memory of Dr. Gross will not lose any of the honor which it deserves.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

THE PRACTICE OF MEDICINE AND SURGERY APPLIED TO THE DISEASES AND ACCIDENTS INCIDENT TO WOMEN. By W. H. BYFORD, A. M., M. D., Professor of Gynæcology in Rush Medical College, etc., and HENRY T. BYFORD, M.D., Surgeon to the Woman's Hospital of Chicago, etc. Fourth Edition. Thoroughly revised, rewritten and enlarged by over one hundred pages, with three hundred and six illustrations. 8vo, pp. xxiv, 820. Philadelphia: P. Blakiston, Son & Co., 1888. Price, cloth, $5.00; leather, $6.00.

This large and handsome volume is one of the best recent productions in the field of gynæcological surgery. It is the work of experienced men, who have observed carefully and studied thoroughly the subject of which they treat. It is fully abreast of the present position of medical knowledge in regard to the diseases peculiar to women, and may be safely taken as a guide in their treatment. We note that the authors, without discussing theoretical questions in regard to it, are firmly convinced of the value of the so-called antiseptic method.

In looking through the book we observe an omission which might be filled by a careful study of the number of the Reporter for January 21, 1888. But omissions are not easy to find in it.

We cannot conclude our notice without a word of praise for the manner in which the publishers have co-operated with the author in making this book attractive and instructive. It contains a very large number of admirable illustrations, a hundred of which have been drawn and engraved especially for this edition; and the illustrations aid materially in making the text clear. We congratulate both the authors and the publishers on the appearance of their work, and recommend it heartily to our readers.

Pamphlet Notices.

A Contribution to the Study of Cysts of the Vagina. By George Woodruff Johnson, A.M., M.D., Washington, D. C., Lecturer upon Operative Gynæcology in the National Medical College, etc. From the *American Journal of Obstetrics and Diseases of Women and Children*, 1887, Nos. 11 and 12. 49 pp.

A Clinical Analysis of Sixty-Four Cases of Poisoning by Lead Chromate (Chrome Yellow) used as a Cake-dye. By David Denison Stewart, M.D., Chief of the Medical Clinic in Jefferson Medical College, etc. From the *Medical News*, December 31, 1887. 21 pp.

Report of a Case of Tuberculous Phthisis, Treated with the Pneumatic Cabinet. By William B. Wood, M.D. From the *New York Medical Journal*, November 12, 1887. 6 pp.

Report of a Case of Wladimiroff-Mikulicz Osteoplastic Resection of the Foot. By Wm. Barton Hopkins, M.D., Surgeon to the Episcopal Hospital, Philadelphia. From the *Medical News*, December 3, 1887. 7 pp. and a table of statistics.

Alumni Society of the Medical Department of the University of Pennsylvania. Proceedings of the Annual Meeting held May 2, 1887, with an Address by John T. Carpenter, A.M., M.D., of Pottsville, Pa. Philadelphia: Collins Printing House, 1887. 23 pp.

The Universal Health Code. By Edward Playter, M.D. Ottawa: Printed by Mason & Reynolds, 1887. 16 pp.

—Dr. Johnson's pamphlet contains an account of a case of multiple cysts of the vagina, upon which he operated in 1887, with a full history and description of this kind of tumors, and a very complete bibliography of the subject. The operation which he regards as the best for cysts of the vagina is that of Schröder, which consists in removing with scissors the part of the tumor-wall which protrudes into the vagina, and stitching the mucous membrane and the lining membrane of the cysts together around the line of the cut. In this way the cyst is turned into the vagina, and the remains of its lining membrane become converted into mucous membrane.

This pamphlet is illustrated with four good wood-cuts.

—Dr. Stewart's studies in connection with a large number of cases of poisoning attributed to the use of cakes artificially colored with chrome-yellow have led to his publication of a paper which is of very great medico-legal value. It is somewhat startling to note that in the sixty-four cases here reported there were eight deaths.

—Dr. Wood's paper contains an interesting account of a case of phthisis in which great improvement followed treatment by means of the pneumatic cabinet, and the result obtained seems to be justly attributed to this treatment. But there may be those who will question the author's sweeping statement that the results of this method "indicate the skill, little or much, that manipulated the instrument."

—Dr. Hopkins is the only surgeon in America, except Dr. Fenger, of Chicago, who has as yet performed this useful operation, which was aptly termed by Wladimiroff, who first practiced it, the operation for the artificial production of pes equinus. It has been well described by Dr. Fenger in the *Journal of American Medical Association*, January 29, 1887, and is well described by Dr. Hopkins in the paper before us, which contains an account of a case in which he obtained an excellent result. The paper is illustrated with two wood-cuts, and contains a table of twenty-two operations. This operation deserves to be better known and appreciated than it has yet been in English speaking countries, and Dr. Hopkins's paper is a valuable contribution to this end.

—This pamphlet is of the character usual to such reports. The address of Dr. Carpenter is interesting, and contains a recommendation that the Alumni of the University of Pennsylvania erect a memorial hall for public exercises. The report of the Executive Committee calls attention to the need of a fuller pecuniary support of the Society by the Alumni in general, and appeals for their aid and co-operation by joining the Society and paying the very moderate dues of one dollar a year.

—Dr. Playter's little tract contains a good deal of sensible advice in regard to a number of matters in hygiene and the treatment of emergencies and accidents. It is apparently addressed mainly to the young, but might be read with profit by persons of all ages.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The *Illustrite Monatsschrift der Aertztlichen Polytechnik*, which recently united with the *Centralblatt für Orthopädische Chirurgie und Mechanik*, announces, in the number for January, 1888, that arrangements have been completed for the publication of a French edition of the united journals, which will be edited by Drs. Leblond, of Paris, and Pasquier, of Evreux.

—The *Journal of the N. E. Va. Medical Society* is an 8vo pamphlet of 22 pages, to be published monthly at Bethel Academy P. O., Virginia, by Thomas W. Smith; price, $1.00 a year. Vol. I, No. 1, is a sprightly number of 22 octavo pages, and contains matter of interest. It deserves the support of the members of the local society, and in later numbers will doubtless give evidence of more careful proof-reading.

—The *Journal of Dietetics* is a periodical published quarterly, at Cleveland, Ohio; price, 50 cents a year. During 1887 four numbers were issued, consisting in all of 88 pages. It has every appearance of being a trade journal, published in the interest of a malt-extract manufacturing company, and does not seem to deserve to be regarded as a medical journal in the ordinary acceptation of this term. The number for October, 1887, contains three articles, one of which seems to be original.

—*The Doctor* is the title of a 12 page quarto-size paper, published in New York, by Charles Avery Welles. It is issued twice a month; price, $2.00 a year. It aims to be chatty and interesting. The number before us is largely occupied by communications from Dr. J. B. Mattison, of Brooklyn, on the subject of narcotic *habituès*, in regard to which he seems to be somewhat of an alarmist. Under the head of "*Omnium Gatherum*," we find many interesting items, some of them decidedly more chatty than dignified. The general plan of the paper is good; but the number for December 1, 1887, does not impress us favorably.

—The *Medical Analectic*, with January 1, 1888, became a weekly journal instead of a monthly. The first number contained 16 pages; the second contained 12. It is made up wholly of abstracts taken from a variety of American and foreign medical journals, very much like the Periscope and Notes and Comments in the Reporter. It is in many respects a very good journal; but we regret to observe that it begins the year by publishing advertisements in its reading pages, with head-lines exactly like those used for its scientific abstracts. This is a course which we think no properly conducted medical journal would pursue, and one against which we think subscribers to medical journals should strenuously protest.

—There is considerable excitement in Brooklyn about the increase of small-pox in Adams street, Willoughby avenue, Henry street and other localities. Since January 23, no fewer than twenty-three cases have been reported.

Correspondence.

Large Brain in a Woman.

Editor Med. and Surg. Reporter:

Sir:—On November 29, 1885, I made an examination of the body of Mary Steele, of Castleton, Vermont, who had died the day before from a prolonged debauch. The autopsy was made by order of the Board of Coroners. I was assisted by Drs. James Sanford and C. C. Nichols, of that town. The woman was of Scotch-Irish descent, unmarried, between 45 and 50 years of age, and nearly five feet ten inches in height. Her features were coarse, and she had a masculine appearance.

She was addicted to drink and brawls. Thanksgiving Day of 1885 was celebrated in such a manner, and in the brawl she was found dead. At the autopsy, the body bore many marks of violence, which even extended through the thoracic walls, and the lungs were found with patches of extravasated blood. The entire intestinal tract was congested. The brain was removed entire; the spinal cord being severed just below the medulla oblongata, and no portion of the dura mater being left attached. The veins on the surface of the brain were turgid with fluid blood; the structure seemed healthy. The organ seemed so large that we were induced to weigh it. Before doing this it was placed on a dry towel, and all the moisture was absorbed from the surface, and light pressure was made upon the organ to squeeze out any that did not properly belong there. The beam tipped quickly at fifty-five ounces avoirdupois. That there might be no doubt about the accuracy of the scales I had it verified with other scales.

Yours truly,

John M. Currier, M.D.

Newport, Vermont,
Jan. 12, 1888.

—In the Pure Food Convention at Washington, on January 20, resolutions were adopted urging the immediate enactment of laws to prevent the adulteration of foods, drinks and drugs. The convention refused to recommend special legislation in regard to lard and oleomargarine. A permanent National Pure Food Association was organized and officers were elected for the ensuing year. A vice-president from each State represented in the convention was also elected. The old Committee on Legislation was continued, but was strengthened by the addition of the President, three secretaries and the reasurer.

Notes and Comments.

Somnambulism Caused by Atropine.

In the *St. Louis Med. and Surg. Journal*, January, 1887, A. D. Williams tells the story of a man for whom he prescribed an atropine solution to be dropped in the eye for contusion of the cornea. The solution was of the usual strength (one grain to two fluid drachms?) and was ordered to be dropped in the eye five times a day. After two or three days of this treatment the patient arose one night towards morning, and in a somnambulistic condition, and clad only in his night shirt, left the house and walked eight or ten blocks away. It was during warm weather, and most of the houses had their windows open. Entering one of these he wandered about the house until awakened by the vigorous snoring of one of the sleepers. Making his way out of the house, he found himself in a strange neighborhood, and had some difficulty in finding his way home, being mistaken once for a ghost. Dr. Williams expresses the opinion that the atropine was the direct cause of the somnambulism, as the man had never before shown the slightest tendency to wander in his sleep. The frequency of application of the drops was diminished and no further ill-effects were noticed. Two other instances in which the drug produced temporary dementia in boys are also mentioned.

Salicylate of Soda for Dysmenorrhœa.

Dr. C. Mettenheimer, of Schwerin, reports in the *Memorabilien*, December 12, 1887, a case of dysmenorrhœa which was greatly benefitted by taking salicylate of soda during her menstrual period. The patient was a woman, thirty-eight years old, who had borne three children. She menstruated regularly, but the flow was scanty and accompanied with colic. She happened to have an attack of rheumatism at one of her periods, and Mettenheimer put her to bed, and gave her fifteen grains of salicylate of soda every hour. After she had taken four doses her rheumatic pains disappeared. At the same time her menstrual flow increased very much, but did not become free enough to excite any uneasiness. It also lasted a day longer than usual. It is not stated that the colic disappeared, although this seems to be implied in Dr. Mettenheimer's communication.

Glycerine Injection for Constipation.

The injection into the rectum of so small a quantity of glycerine as from a third to a half of a fluid drachm is said to produce a

stool in obstinate constipation in children or adults. In the *Memorabilien*, December 12, 1887, there is an abstract from the *Wiener med. Presse* in which the effects of the method and its mode of operation are well described. The results attributed to it there certainly invite to its trial.

New Blistering Liquid.

D. Boni (*Giorn farm. trent.*) recommends chloral camphor as superior to any of the ordinary vehicles for the active principle of cantharides. His preparation consists of

Camphor	20 parts.
Chloral hydrate	30 "
Cantharides	10 "

The pulverized camphor is mixed with the chloral hydrate and heated to 140° F. until fused, the bruised cantharides is then added, and the mixture digested at 140° to 158° F. one hour, with occasional stirring, then strained and preserved in a glass stoppered bottle. It is to be applied by a compress, or in the case of children or delicate women, simply pencilled over the surface. The circumstance that it is non-volatile gives it a great advantage over cantharidal collodion.—*Quarterly Therap. Review*, January 1, 1888.

Application for Gout and Rheumatism.

A mixture made up of

Ether	15 parts
Flexible collodion	15 parts
Salicylic acid	4 parts
Morphine	1 part

painted every hour on joints affected with gout or chronic rheumatism is said to afford great relief from pain.

Aspirating the Heart.

M. Budin thinks that puncturing the heart is practicable and not dangerous in the majority of cases, and that it is destined especially to remedy the dilatation of the right heart when there is no organic lesion. He recommends that the aspirating needle should be inserted in the third intercostal space on the right side, and close up to the edge of the sternum in aspirating the auricular cavity. When the ventricle is to be aspirated, the needle should enter the fourth intercostal space on the left side close to the left edge of the sternum. Puncture of the ventricle should be preferred, as the cardiac wall is much thicker and less prone to tear, and thus exposes less to hemorrhage into the pericardium. Cardio centesis acts as a depleter of the right heart, and might give great relief to a distended heart.

False Charge against a Physician.

The *Lancet*, January 14, 1888, states that false charges of an infamous character against medical men are too common. But one of a singularly audacious and mendacious nature has met with signal exposure and retribution in Ireland. An action was brought against Dr. Henry Davy, of Terenure, county Dublin, to recover damages ($5000) for alleged criminal connection with the plaintiff's wife. Three witnesses for the plaintiff in succession, his daughter-in-law, servant and daughter, said they had been offered money to swear falsely against the defendant, and had not a word of evidence to give against him. It seems that the mother had kept the family for years, and that the father and plaintiff was a ruffian and villain, who had always treated his wife and family in a shameful manner. The Recorder said that in all his experience he had never known a more atrocious or infamous case, or a more scandalous attempt to ruin a wife and to obtain money. He ordered the Crown Solicitor to prosecute the plaintiff for perjury.

Unique Method of Inducing Abortion.

Dr. A. Harris reports in the *Journal of N. E. Va. Medical Society*, Jan., 1888, that he was requested to see a case of alarming menorrhagia, at night, in an unmarried patient. The hemorrhage had begun some twelve hours before, and there had been suspension of the menstrual function for four months, which was ascribed to the patient having "taken cold." A digital examination revealed the presence of an ovum, which extended into the vagina and was removed and placed in a napkin. Although the mother and aunt of the patient were in her room during the whole of the doctor's visit, neither had ever suspected that her illness was due to any other cause than suspended menstruation caused by getting her feet wet.

Abortion was induced by the application of ice over the hypogastrium for twelve hours consecutively. The patient was led to try this expedient by the general belief that a mare would lose her foal if made to ford deep water in winter.

Constipation in Children.

Bouchut recommends:

℞ Podophyllini ..... gr. j
Alcoholis ..... f℥iss
Syrupi althaeæ ..... q.s. ad. f℥iv
M. Sig.—Dose a half teaspoonful in tea a day.

—*Revue Internationale des Sciences Médicales.*

NEWS.

—Diphtheria is reported to be epidemic at Rittersville, a village of about two hundred families between Bethlehem and Allentown, Pennsylvania. About forty houses are infected, and a number of deaths have occurred.

—Dr. Manson, an English physician, has been summoned from Hong Kong to take medical charge of the young Emperor of China. This is said to be the first occasion on which a foreign doctor has ever attended a member of the imperial family.

—Dr. Addinell Hewson has been appointed by the Faculty of Jefferson Medical College to lecture to the classes in anatomy, at that institution, during the illness of Prof. William S. Forbes, M. D., who is confined to his home by an attack of erysipelas.

—A congress of physicians and veterinarians will be held in Paris from July 25–31, 1888. Any physician or veterinarian may become a member by registering and paying a fee of ten francs ($2.00). The subjects for discussion proposed by the committee on organization are:

1. The dangers incident to the use of meat or milk from tuberculous animals, and the way to escape them.
2. The human races, the species of animals, and their organic surroundings in respect to their proneness to tuberculosis.
3. The channels for the introduction and for the propagation in the economy of tuberculous virus, and measures of prophylaxis.
4. Early diagnosis of tuberculosis in man and in animals.

Other subjects may be discussed by members of the Congress, if they choose.

HUMOR.

Mrs. Partington says her son Ike shall not have a guitar. She says he had it once when he was a baby, and it nearly killed him.

A doctor who wished to sell a horse was asked if the animal was timid. "Not in the least," he answered, "he often spends whole nights alone in the stable."

Sidney Smith was told one day that one of the giraffes at the Zoological Garden had caught a cold. "Just think of it," said he, "an animal with two yards of sore throat!"

A doctor who was prescribing for a patient with rheumatism sent him off with the request: "If this does you any good I wish you would let me know, for I am a great sufferer with rheumatism myself."

OBITUARY.

ROBERT A. GIVEN, M.D.

Dr. Robert A. Given, of Burn Brae, Clifton Heights, Delaware county, died Tuesday, January 10, in the 73d year of his age.

FREDERICK FLETCHER, M.D.

Dr. Frederick Fletcher, a resident of Bradford county, Penna., died suddenly in Wilkesbarre, Thursday, January 18, of paralysis, at the age of 70 years.

W. B. WILSON, M.D.

Dr. W. B. Wilson, a leading physician of Southern Illinois, died at Flora, January 17. His death was the result of blood-poisoning from malignant carbuncle. Dr. Wilson was for many years the chief surgeon of the Ohio and Mississippi Railway.

DR. ADOLPH LIPPE.

Dr. Adolph Lippe died on January 23, 1888, at his residence, No. 1204 Walnut street, after a brief illness of three days. Dr. Lippe caught a severe cold which resulted in pneumonia. He had been in feeble health for weeks, and from the first hour of his illness seemed to despair of his recovery. He was one of the best known homœopathic practitioners in Philadelphia. He was seventy-six years old.

HENRY INSLER, M.D.

Dr. Henry Insler, an old resident and well-known physician of Houghton county, Michigan, died January 18, 1888, at the home of his son in Calumet, at the age of 84 years.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Jan. 22, 1888, to Jan. 28, 1888:

Capt. H. G. Burton, Assistant Surgeon, granted leave of absence for one year on S. C. D., to take effect when able to travel. S. O. 19, A. G. O., January 24, 1888.

First-Lieutenant W. W. R. Fisher, Assistant Surgeon, granted leave of absence for one month, on surgeon's certificate of disability. S. O. 4, Dept. Cal., January 20, 1888.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Jan. 28, 1888:

W. A. Wheeler, Passed Assistant Surgeon, granted leave of absence for thirty days. January 24, 1888.

J. H. White, Passed Assistant Surgeon, granted leave of absence for two days. January 26, 1888.

R. B. Watkins, Assistant Surgeon, granted leave of absence for thirty days. January 28, 1888. Resignation accepted, to take effect March 15, 1888. January 28, 1888.

G. T. Vaughan, Assistant Surgeon, appointed an Assistant Surgeon, January 25, 1888, *vice* A. D. Bevan, resigned; assigned to temporary duty at Marine Hospital, Boston, Mass. January 26, 1888.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.
The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

THE TREATMENT OF CARBUNCLE WITH CARBOLIZED SPRAY*.

BY PROFESSOR VERNEUIL,
PARIS.

Reported by Arthur C. Hugenschmidt, M.D.

For nearly forty years, during which time I have been practicing surgery, I have seen a great variety of methods employed in the treatment of carbuncle, and have observed that these methods tend to become less and less surgical or operative, but are no less efficacious on that account. At the beginning of my practice, like others, I treated this affection by very deep and long incisions. But I soon observed that this cruel practice was really not at all necessary, that it was even dangerous sometimes, and that in the majority of cases recovery was just as rapid without this proceeding. I then recommended, sometime ago at the Société de Chirurgie, to use the knife only in cases in which pain was violent, and when the disease showed a tendency to spread rapidly, leaving to themselves those which were not very painful or in which the affection was circumscribed.

As soon as Paquelin's thermo-cautery was introduced into practice, I substituted its use for that of knives, which often aggravates the disease by leading to septicæmia, hemorrhages, etc. I made deep and multiple openings, disposed in rings over the affected parts, plunging the cautery into the healthy parts all around. The dressing was an antiseptic carbolized one. The objection to this method was the time it required. When the lesion was extensive, as many as one hundred and fifty cauterizations were sometimes necessary, and they took at least twenty to thirty minutes to carry out—the patient being, of course, obliged to be put under the influence of chloroform.

In 1881 I had established the following rule: "Exceptional intervention only in grave and well-marked cases; but applied with energy." I varied my modus operandi, however, according to circumstances; and instead of using both the cautery knife and the cautery point, I used only the latter.

Such was my practice when, in 1883, I saw a very grave case of carbuncle situated at the posterior region of the neck in a man of strong constitution, but who was suffering from well-pronounced diabetes. The carbuncle was opened at its centre, and was progressing rapidly notwithstanding numerous incisions had been made with the cautery, and the wound had a very bad odor. On my first visit I decided that additional openings would be required, and that I would make them the next day. In the meanwhile I ordered the wound to be twice sprayed for one hour with a two per cent. solution of carbolic acid. On the next day the wound had no odor, and considerable diminution of the redness and swelling had taken place. I then resolved to try this method further.

Since then I have used the sprays exclusively against *all* carbuncles—small, medium or large; diabetic or not; painful or painless; still closed, or opened naturally, or by artificial means. This very simple mode of treatment I found superior to all others, in stopping the sufferings soon and in rapidly limiting the extension of the disease.

Amongst the cases I have treated, I may cite that of a young professor of the Paris Faculty of Medicine, who died lately of diabetes complicated with albuminuria. He

* A paper read before the Academie de Médecine, of Paris, January 17, 1888.

had a very large furuncle, or boil, on his left cheek, with diffuse and deep extension and considerable surrounding œdema. The prognosis was grave, not only on account of the seat of the trouble, but also on account of the presence of sugar, 3.5 per cent. Cardiac and pulmonary lesions rendered the administration of chloroform dangerous. I resorted to the carbolized spray. After the first application the œdema disappeared, the pain diminished and disappeared entirely in forty-eight hours; and after seven or eight days, in six of which the spray was used four times, the large furuncle was reduced to a medium-sized ecthyma pustule; and it was entirely healed by the seventeenth day.

Of course, this treatment will not prevent accidents which may occur when the carbuncle has given rise to an extensive sphacelus in extremely cachectic patients. But in the majority of cases, if taken early, we have in the spray an abortive treatment for carbuncle.

The manner of using the carbolized spray is known to every surgeon. A convenient apparatus is the atomizer, which is heated by alcohol, and which will work for twenty-five minutes. Such an one is sufficient for small or medium sized carbuncles, and for those which are already opened. For the large tumors, where the skin is not broken, it is better to use a more powerful apparatus, which gives off a more abundant vapor and has a more considerable force of penetration. The apparatus is placed from one to two feet from the skin, regulating the spray according to the sensation of the patient. I generally place nothing between the carbolized vapor and the wound, or I place there only a single thickness of transparent gauze. Up to this date I have used only the two per cent. solution of carbolic acid. I have not tried other antiseptic solutions, being contented with the results obtained with carbolic acid, which, in my experience, has never irritated the skin nor produced any symptoms of general disturbance. The number of applications of the spray is variable. Usually three or four sittings, of half an hour each, every day, are quite sufficient. Between the time of spraying, an antiseptic carbolic dressing should be applied to the lesion. The patient might find so much relief from the spraying, that the sittings could be made much more numerous—six or eight a day. The following precautions must be taken in this method: 1. Carefully protect the normal parts surrounding the carbuncle with compresses, rolled napkins, perforated cushions, or pieces of adhesive plaster perforated at the centre, according to the region which is occupied by the lesion; at the same time protecting the patient's linen and bed-clothes from becoming wet. 2. Place the patient in an easy position, so that he shall not be tired during the spraying. When the boil, or carbuncle, is at the back of the neck, or on the back, the patient should be seated on a chair, so that he can rest his folded arms on the back of the chair. When the disease is situated in the perineum, or near the anus, the lithotomy position is the best; and when it is in the lateral, lumbar or gluteal regions, the patient should lie on the side with the lower limbs flexed.

The treatment by the carbolized spray is not only very simple, but also adapted to all forms or phases of the disease, being the same from the first day to the last. When used at the beginning for a small carbuncle or boil, it has a good chance of aborting it entirely. Later, when the swelling is voluminous or has a tendency to increase, it will stop its progress. Later still, when mortification and perforations of the skin have begun, it limits the sphacelus, helps to the separation of the mortified tissues, disinfects the wound, keeps it clean, and by so doing reduces the temperature and the symptoms of general disturbance. Its advantages are increased by the fact that its application does not demand the use of chloroform, and that there is no need to touch the tumor or irritate it in any way. I have said, and I repeat, that the old method of incision with the lancet was far from being innocent, that these incisions produced in enfeebled patients severe hemorrhages, which were difficult to arrest, and which necessitated the use of painful hemostatics; and that they were capable of developing septicæmia, of propagating gangrene, and of favoring the absorption of putrid matter.

Many surgeons after having opened a carbuncle freely, scrape, excise or press the spongy mass to evacuate the pus and gangrenous materials. But these proceedings are at the same time dangerous and painful, and should be absolutely avoided; for the use of carbolized spray renders them unnecessary, by disinfecting the wound.

In order to appreciate the danger of using force on a carbuncle or furuncle, one must remember that the affection is of an infectious character, and that the tumor contains pathological microbes capable of extending on the surface, or of colonizing in the interior, by auto-inoculation, or by entering the general circulation.

This last fact is not as well known as it might be, although it is known that a car-

buncle, and even a boil, is capable of giving rise to fever, general symptoms, and even visceral manifestations—albuminous nephritis, and deep abscesses, for example.

In conclusion I would state the following views: 1. Furuncle and carbuncle are only different stages of one infectious disease, and are to be treated by the same therapeutical means. 2. The treatment consists in surgical interference or medical applications. The first was formerly thought to be indispensable, or at least was resorted to in the majority of cases. The second were thought to be efficacious only in mild cases, and were employed as secondary measures for relief. 3. To-day surgical intervention is becoming less and less necessary, and should be reserved for exceptional cases; on the other hand, antiseptic solutions of carbolic acid, of boric acid, etc., used in a peculiar way, and especially under the form of prolonged and repeated atomization, are remarkably efficacious, while they are at the same time very simple and free from danger. 4. Sprayings, with very few exceptions, lead to a rapid recovery from the manifestations of furuncle or of a small carbuncle, and they check the disease in graver cases. They very rapidly put an end to the pain, the fever and the general symptoms; they disinfect the purulent and gangrenous spots, and assist the cleaning of the lesion and the formation of granulation tissue. 5. Sprayings may be used in any region of the body for all forms, and in all the stages of the disease. They are never dangerous, and will alone bring on a cure in the majority of cases. They would also help greatly to the success of surgical interference, if such should be deemed necessary. 6. Finally, they prevent internal auto-inoculations and the phenomena of general infection.

—A fire occurred in the Hospital for the Ruptured and Crippled, in New York, on the evening of January 29. There were 163 crippled children in the building under treatment, and the youngest were in bed. The fire was discovered by two girls, both suffering from spinal disease, who notified a nurse. An alarm was given, and all the children were got out safely, the guests in the Vanderbilt Hotel opposite giving up their rooms for their accommodation. A 10-year-old boy, who is suffering from hip disease, tried to carry out a little deaf and dumb cripple, but the boy was too heavy. He then dragged him out to the hallway, where he met a policeman who carried both boys down. The fire was incendiary, the guilty person being one of the inmates, a little girl.

Communications.

SOME OPERATIONS ON HERNIA IN THE PHILADELPHIA HOSPITAL.

Reported by
EDWARD MARTIN, M.D.,
SURGICAL REGISTRAR.

Case I.—Michael Carter, glassblower, aged 36; right scrotal hernia, four years' duration, caused by a fall; had reached size of a baby's head when he began wearing a truss, one year ago. At times it would come down under the truss, but could be easily reduced.

Nov. 13, 1887, it came down early in the morning; the patient continued to work for some hours, then tried to reduce it, but unsuccessfully. He was received into the surgical ward the same afternoon. Ether was given and gentle efforts at reduction made, but in vain; pain and tenderness steadily increased; constipation obstinate, but no vomiting. Operation at midnight, by Dr. William S. Janney. Incision over tumor eight inches. Small intestine found in sac; no omentum (indirect inguinal, right side). Constriction at internal ring relieved and gut returned. Sac dissected up and sewed across with continued sutures of carbolized silk, the same thread then being passed through the conjoined tendon and out to the junction of the middle and inner thirds of Poupart's ligament, piercing it at that point; the latter structure being drawn as strongly as possible toward the middle line of the body. The sac was cut off below the line of sutures, crossing it; the wound was drained and closed with silver wire. The course of the case was typically aseptic. Temperature next day, 100°; thereafter normal till the eighth day, when, the bowels being opened, it immediately dropped again to normal. No suppuration. Cure apparently radical.

Case II.—Robert Taylor, white, aged 56, laborer; long-standing scrotal hernia, size of a large fist; much pain and constant dragging sensations. Operation for radical cure by Dr. Janney. Skin pinched up, and an opening three inches long made through integument by transfixion. The middle of incision was over the external ring. Careful dissection down to sac, which was found so extensive and closely adherent to surrounding cellular tissue that it could not be entirely separated. The freed portion was invaginated and stitched to the internal ring. The columns of the external ring were brought as near

together as possible. The wound was closed, drained, and dressed antiseptically. Suppuration the second day; temperature 102⅖°. The discharge of pus became shortly very profuse, burrowing into the scrotum, and requiring a counter-opening. This continued for four months, till the man had reached an extreme degree of emaciation; the discharge then gradually grew less, till in two months more the wound was entirely closed, and the man's body-weight greater than at the time of the operation. Four months after leaving bed the cure was still satisfactory. There was a hard cicatrix, occupying the position of the inguinal canal and extending into the scrotum. The man was able-bodied, and expressed himself as well satisfied with the result.

As observed by Dr. Janney, this case is of value as illustrating a cure in spite of a very violent inflammation and free suppuration following an operation in which much liberty had been taken with the peritoneum. The cure in this case was certainly rendered more permanent by the inflammation.

Case III.—Eliza Moran, white, aged 70, domestic; married, and has five children. There has been a lump coming and going in the left groin for four or five years. On each appearance there would be cramps and vomiting, lasting from a couple of hours to a day; the lump would then become somewhat smaller, and active symptoms would cease. There would be much wind passed from the bowel, and the patient would shortly be as well as ever.

One morning the hernia came down again; pain and cramps steadily increased till evening of same day, when she was admitted to the surgical ward. Palliative treatment was employed; the symptoms were progressive; stercoraceous vomiting beginning.

The operation was performed by noon of next day, by Dr. William G. Porter. The tumor was the size of a Bartlett pear and distinctly triangular in shape, occupying the left groin. An incision three inches long was made directly over the tumor and the sac opened, the constriction being at its neck. Three knuckles of intestine, giving the tumor its peculiar shape, and a mass of omentum the size of a man's palm, were found in the sac, all much congested. The bowel was readily returned after relieving the constriction; the omentum being adherent it was ligated and cut off, the stump being returned to the peritoneal cavity.

Following the operation the patient became delirious and tore off her dressings; there was shortly very free suppuration, but in spite of this she rapidly recovered.

Case IV.—Norah M., white, aged 40, domestic, very fat. There was a history of old ventral hernia, of four years standing. She was a multipara, and has had a laparotomy done upon her.

On April 17, sudden acute pain and vomiting, with constipation, occurred. She was admitted on April 20. There was very profuse fæcal vomiting; constant pain, with agonizing paroxysms; great prostration; abdomen tense and swollen; on palpitation a tumor, the size of a child's head, lying between the ensiform cartilage and umbilicus, slightly toward the left side, presenting the ordinary signs of a strangulated gut.

An operation was immediately performed by Dr. George McClellan. An incision six inches in length, from ensiform to umbilicus was made. Two apertures were found in the linea alba, above and apart from the umbilicus. Through the upper protruded about four feet of small and large intestines, covered by an old thickened and adherent sac. Through the lower and recent rent, protruded about eighteen inches of small intestine, in a state of livid congestion. Omentum slightly developed. The gut was reduced, and the walls of the abdomen, together with the peritoneum, fastened by gut sutures.

During the operation and until death, which occurred a few hours later, constant and copious stercoraceous vomiting persisted. To rid the stomach of fæcal matter, the stomach-pump was used, with apparently some benefit. The extremely exhausted condition of the patient prior to operation left her no reactive power, and in spite of a free use of diffusible stimulants, she steadily sank.

Dr. McClellan remarked that he fully believed in the use of the stomach-pump in such instances, being confident that large masses of fæcal matter and gases, even though there was but little absorption, exert a distinctively unfavorable effect upon the patient, far more marked than the disturbance incident to passage of the stomach-tube.

Case V.—William J., white, aged 35, a dyer, was admitted to the surgical ward on May 29, 1887, with history of long-standing inguinal hernia, for which a truss had been ordered but not regularly worn. Two days before admission, his truss being off, the hernia came down, and he was unable to reduce it. Pain and tenderness shortly set in, followed by some vomiting. On admission the vomit was not stercoraceous; the hernia, a right oblique inguinal, was extremely tender, about the size of a walnut, and could not be reduced. Operation was at once performed by Dr. John B. Deaver. An in-

cision was made directly over the tumor. This hernia proved to be an encysted hernia, or the "infantile hernia of Mr. Hey, of Leeds." This Dr. Deaver clearly demonstrated. Opening first the anterior layers of a patulous tunica vaginalis, the true hernial sac was exposed; this was in turn opened, and some adhesions between it and a knuckle of intestine broken up, when the bowel was readily restored to the abdominal cavity. The redundant hernial sac was cut away, and its neck stitched across with cat-gut interrupted sutures. The tunica vaginalis was separately stitched with cat-gut, and finally the wound was closed with silver wire. The operation was strictly aseptic in performance and sequel, the patient made an uninterrupted recovery, and is apparently radically cured of his hernia.

ECLAMPSIA AT END OF THIRD STAGE OF LABOR, AND COMPLICATED BY POST-PARTUM HEMORRHAGE.

BY R. B. McCALL, M.D.,
GEORGETOWN, OHIO.

Mrs. K., aged 33, a brewer's wife, and mother of three healthy living children, was confined for the fourth time, July 1, 1869. The previous labors had been natural and unaccompanied by a single untoward event. Gestation had been uninterrupted, and the present labor seemed to be as auspicious as any that preceded it. In due course the third stage supervened, the head descended and engaged in the vulvar opening. But suddenly, as it made its escape, my attention was arrested by a peculiar vibration or tremor of the body; and glancing at the face, I perceived that it was distorted; the woman was in the throes of eclampsia. The child was speedily delivered and the cord compressed. On pressing the hand gently through the vulva, the placenta was found occupying the vagina, and it was readily extracted. With the removal of the placenta came such a torrent of blood as I hope it will never be my fortune to witness again—so voluminous that it seemed death must be instantaneous and inevitable.

The muscles relaxed, the face became blanched, the eyes rolled back in their sockets, the jaw fell, and the woman appeared to be dead. The bed was saturated with blood, and a crimson stream flowed across the floor to the open fire-place, a distance of twelve feet. I was stunned for a moment, but only a moment, when I rallied all my resources; and although it seemed like an effort to restore the dead, to bring back life to a body from which the vital spark had passed forever, yet by that strange instinct which animates the heart and actuates the physician in the most appalling situations of his professional calling, I promptly sought and brought into requisition all the measures then known and used by the *accoucheur*.

Not only did I work with all my might and intelligence, but induced others to labor with a celerity and energy that was indeed commendable. The first thing done was not to pour, or attempt to pour, stimulants or restoratives down the throat, but to provoke efficient contraction of the inert uterus, if indeed there was any contractility left in it; and to this end a half-gallon of cold water drawn fresh from the bottom of a well in the porch, but a few feet away, was dashed from a considerable height on the exposed abdomen, and the operation was once repeated. The uterus became a firm, round, contracted mass. Hemorrhage was instantly stopped, but, alas! possibly too late for the welfare of the mother.

At this juncture attention was directed to measures of restoration. There was present that peculiar Hyppocratic physiognomy, or a very near approach to it, which says as plainly as articulate language can express it, that life is extinct: mouth open and jaw fallen, eyes turned up and filmy, surface pallid, bloodless, no pulse at either wrist, temple or elsewhere; no breathing that could be appreciated by the senses as such. Notwithstanding, by a very careful auscultation, the heart was found to pulsate very feebly, and with intermitting movement, like the slow, progressively-failing oscillations of the pendulum when the motor that impels it has ceased to act; moribund describes, in a word, the condition.

Bedford in that day was quite popular, and his methods at the bedside of the parturient woman were accepted without question. A suggestion of his in a case of the kind above described was to administer laudanum in heroic doses, in conjunction with brandy or not, in a teaspoonful dose.

Well, the tincture was administered in that dose and repeated, and afterward given at short intervals in diminished doses, till evidence of reaction was seen in the renewed manifestation of the vital functions. There was neither whisky nor brandy at hand. I was therefore obliged to put my trust entirely in the opiate. Whatever may have been Dr. Bedford's theory of the *modus operandi* of the drug in similar cases, and however contrary it may seem to certain preconceived notions concerning the physiological action of

opium, it does seem to possess marvellous stimulating powers in conditions characterized by great exhaustion resulting from vascular depletion. Its effects were truly magical. Early after its exhibition there were apparent signs of returning animation; first a slight, barely perceptible fluttering of the heart, a very faint, hardly appreciable vibratory thrill of the radial artery, and a faint sighing. But it was a long while before any hope could be reasonably indulged in.

At the end of a few hours the flickering flame of life had been so far restored as to afford ground to believe that, with careful nursing, future recovery was an assured fact. On the day following the wan, pallid, lifeless body of a few hours previous would scarcely have been recognized in the smiling countenance of the mother, happy in the possession of her infant, and the joyous congratulations of family and friends. It is almost marvellous with what rapidity return to strength and health is effected from conditions so perfectly similating death.

In conclusion I desire to call attention to the fact that in this instance life was saved through the prompt use of the readiest and most efficacious means at hand, namely, cold water. Other measures are urged as the most suitable in these desperate straits, such as the injection of hot or cold water, mixed or unmixed with vinegar, or some other astringent, or of a solution of persulphate of iron (Barnes), but the application of these demands delay, and during the time thus lost a few or many more ounces of blood will make all the difference in the world, and, through an unfortuitous concurrence of helpless nature and art, life ceases. If cold or iced water is not at hand, and hot water is, by all means use the syringe. Nothing, perhaps, could excel it in such an emergency. Should nothing better offer, introduce the hand into the uterus, make friction on its internal surface, while the other hand grasps the organ from without. An old practitioner assures me that this manœuvre succeeded admirably in a case of his, where he failed with other devices. However, in that class of appalling accidents where a moment's time lost may cost a life, if cold water can be procured—simply the cold douche—it will *rescue* life; although it must be confessed that it seems to be a rude and primitive method of application. True, a measure of effect, possibly enough in most instances, may be obtained by the use of cloths dipped in cold water and laid on the abdomen, to the thighs and vulva. But this lacks the additional force communicated by the fall of the liquid, a very important consideration. It may be urged that such practice should be discountenanced except as a *dernier ressort*, for the reason that if the lady and her friends could be consulted they would undoubtedly raise most serious objections. Let it be stated, *per contra*, that when the conflict is a hand-to-hand affair between the physician's method and the forces of the King of Terrors as to who shall have possession, it is no part of professional duty to stop to consider anybody's taste, inclinations or feelings, but to act at once, without unnecessary delay, and with all the intelligence at command, that, by the help of God, a life may be saved from almost certain dissolution. The writer has had occasion to use the douche on these occasions, and never with any misgivings as to the result. No evil was ever observed to follow it.

An aged practitioner, Dr. A. M. Ellsbury, informs me that he knows the method was a popular one over a hundred years ago. He was called to see a lady who was flooding severely, and used such applications as were in vogue at that time (1845), and known to him, then a young physician, but with little avail, when the mother-in-law, aged 96 years, told him that in her first labors she had copious hemorrhage, that her physician placed her in the recumbent dorsal posture on the hard floor, caused the nether extremities to be elevated, when he poured cold water on the vulva, then dashed it over the abdomen, and, lastly, all over the body. This was indeed primitive, but as the ancient great-great-great-grandmother truly averred, it accomplished the desired result effectually.

"In cases of extreme gravity, where the impression has been sudden and profound," my esteemed friend, Dr. W. W. Ellsbury, whose experience has been great, prefers to place reliance on the douche, yet in "cases not indicating such heroic treatment" he would make friction on the inner surface of the womb, while grasping the organ from without with the other. Of course it is not claimed that this would be the most desirable method in cases in which other and possibly less disagreeable means would answer equally well. Nor is it suggested by anything said above that an experienced practitioner would be guilty of the blunder of applying restoratives by the mouth or hypodermically before taking suitable steps to suppress the flow of blood; but, at the same time, let it be added that it is hoped the hint may not be lost on the young practitioner, who, although

his attainments may be excellent in their way, yet lacks bedside observation and the practical lessons thereby enforced. Arrest hemorrhage first, *then* use restoratives. Opium, as has been seen, is perhaps the best where there is great exhaustion; brandy, whisky or wine may be used to advantage. Ethereal preparations, by mouth or rectum, if practicable, or preferably given by hypodermic injection, are sometimes found very effectual in stimulating the respiratory centres. In cases where the indications are not so imperative, hot water injected into the uterine cavity is deservedly preeminent. Indeed, if it could be employed in those graver complications it would have to be considered the remedy *par excellence*.

A great advantage from its use is that relaxation does not subsequently occur, bringing a recurrence of the flooding, which is frequently the case after the injection of cold water or the introduction of ice. A simple, common-place device, and one oftentimes had recourse to by the country physician, is to carry the hand, grasping a sponge or folded cloth, saturated with strong cider vinegar, into the uterus; the sponge is squeezed, the vinegar flows around the wall, constricting the mouths of the open vessels. In all cases where it can be done firm external compression of the uterus should be made.

The question of shock might be raised. That is to say, that the douche as used is capable of inflicting a great shock on the already depressed and struggling powers of nature, and so precipitate the event it was designed to anticipate and preclude. It may be answered that, so far as known, instead of precipitating dissolution, it has in all instances, when applied in time, been the fortunate agent to avert that end. Doubtless the douche performs the two-fold function of an irritant (vital dynamic) and that of a mere physical dynamic. One eminent *accoucheur* whips the abdomen with a towel that has been dipped in cold or iced water, and to this innocent and effective mode it is objected that it could never be popularized in practice among the higher classes.

Can it be that the higher classes must be denied an advantage, a great boon it might be called, which their less favored sisters enjoy?

What became of the convulsions in the present case? There was but the one described; subsequently there were no signs of a recurrence. The history of eclampsia shows that frequently when convulsions take place under the circumstances alluded to there is but one, usually very severe. This doubtless was an example of the kind, for it is not probable that the chilling shock would have brought about a result contrary to knowledge and observation.

HEART DISTURBANCES IN CHILDREN DUE TO DISTENSION OF THE RIGHT AURICLE AND PULMONARY ARTERY.

BY JOHN M. KEATING, M.D.,
PHILADELPHIA.

In an interesting article by Martin de Gimard in the *Revue Mensuelle des Maladies de l'Enfance*, upon the relations existing between the right heart and diseases of the liver—an association as frequent as between those of the left heart and the kidney—there is the report of an interesting case, which may be summarized as follows: The subject was a boy 11 years old, who had hypertrophic cirrhosis of the liver without jaundice. There was nothing in the antecedent history of the case to attract attention. In 1887 an enlargement of the abdomen was noticed; the boy complained of a daily increasing difficulty in buttoning his pantaloons; and in addition, he had attacks of vomiting. These were the principal symptoms; another, which was brought out by questions, was that his face became deeply cyanosed after running from school; indeed, his father frequently scolded him "for getting ink on his lips." These symptoms increased rapidly, and the boy soon had slight panting after walking and some œdema of the lower limbs, and small quantities of albumin were found in his urine. Dr. Cadet de Gassicourt saw the case, and hesitated in his diagnosis between a primary affection of the heart and one of the liver. After a time the abdomen was tapped, and a large amount of fluid was evacuated; an enlargement of the liver was detected, and the diagnosis was established.[1]

The feature in this case which interests us most is the condition of the patient's heart. There was great dilatation of this organ, but there had never been a murmur while the child was in the house—though there was a marked clacking second sound over the area of the pulmonary artery—nor had there been any pulsation in the jugular veins. This case evidently represented a typical condition of cardiac enfeeblement and engorgement, with dilatation of the right heart, caused by a primary hepatic affection.

Gimard discusses the question of cardiac

[1] In the *Revue Mensuelle des Maladies de l'Enfance*, Laurent and Honoret have reported fifty-one cases of cirrhosis of the liver in children.

sounds in cases of hepatic cirrhosis, and quotes some observations of Laurent in his thesis on this subject. In one case of atrophic cirrhosis there was intense dyspnœa, double pulmonary congestion, and œdema of the lower limbs. In this case there was a systolic murmur over the aortic area, which was supposed to be dependent upon aortic stenosis; but at the autopsy *the valves were found normal*, and the right heart dilated and engorged. The post-mortem appearances in all the cases noted were similar.

There are so many conditions of the system which will produce cardiac weakness that it presents a most interesting study in children's practice. The affections of the right heart in children have scarcely received the attention they deserve, especially those which are functional.

In the ordinary position of the heart, a moderate degree of distension of the right auricle and ventricle will not cause any encroachment on the vessels as they are given off; but, if the right auricle becomes distended to any very great extent, in all probability a certain amount of pressure would

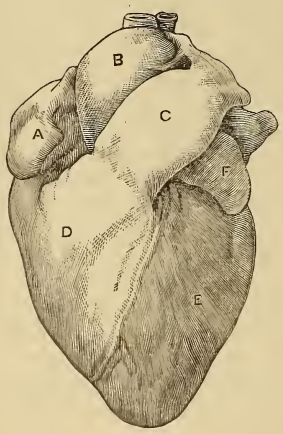

Fig. 1.

A. Right auricle.
B. Aorta.
C. Pulmonary artery.
D. Right ventricle.
E. Left ventricle.
F. Left auricle.

be produced upon the aorta, and just at that portion where a constriction would cause a systolic murmur. This would be the more apt to take place if the pulmonary artery was also over-distended. As I look at a specimen which I have before me as I write, I cannot but feel convinced that the theory I have just offered in explanation of the systolic *bruit* in anæmic children, and in those in whom the heart-muscle is worn out or the nerves are toneless or exhausted, is tenable. A glance at the diagram which I have drawn from nature, I think, shows this condition.

Figure 1 represents an antero-posterior view of the heart, with the right auricle empty and the aorta of normal size.

In studying the specimen, I carefully distended the auricle and pulmonary artery with soft cotton, being careful not to over-distend it, but simply to fill out its relaxed tissue. I then placed the heart on edge, as it were, so as to show almost the whole right auricle except that portion behind the aorta. From

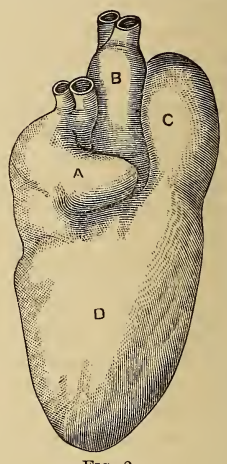

Fig. 2.

A. Right auricle.
B. Aorta.
C. Pulmonary artery.
D. Right ventricle.

this view, which is shown in Fig. 2, it will be seen that the aorta is distinctly narrowed in calibre by such distension of the vessels as I practised. This experiment has suggested to me the important question, Can the systolic murmur which is noted in the cases of Laurent, without any aortic lesion, and the enormous congestion of the right heart after death, be explained by the reciprocal pressure exerted by a distended auricle and a distended pulmonary artery?

My attention has been recently called to another peculiarity of the cardiac rhythm, which, though at first I believed it was confined to children, is, I am now satisfied, frequently found in nervous, worn-out hearts of anæmic adults, and especially of young women and young men.

This peculiarity consists in an irregularity in the impulse of the heart, which is dependent upon respiration, and is probably due to a choreic movement of the right heart when it finds itself deprived of its blood-contents by the sudden exit of its blood in expiration. The heart, in health and in the adult, is a well-toned muscle, capable of accommodating itself to all circumstances. In childhood, and especially in rapidly-growing children and cases of anæmia or chlorosis,

the heart-muscle keeps its tone when the stimulus of blood within its cavity is felt. As the air leaves the lungs, the pulmonary artery is called upon immediately to supply blood to its radicles, and when the heart is deprived of this stimulus, its action becomes at once excessively rapid and possibly irregular. During normal breathing, the heart's action will be noted as rather quick or possibly weak; when the breath is held, it will gain strength and be slower; but during forcible expiration it will become irregular, and possibly intermittent, and excessively rapid. I believe these phenomena to be, to a certain extent, normal in childhood; but when adults exhibit a *puerile heart*, it is undoubtedly an evidence of weakness of the heart-muscle—a weakness which is distinguishable from the ordinary functional disturbances of hearts under the influence of tobacco, and I believe particularly limited to the right heart.

TREATMENT OF RUPTURE OF THE PERINEUM.

BY ARTHUR E. SPOHN.
CORPUS CHRISTI, TEXAS.

This morning (October 21, 1887) I removed the stitches from the perineum of a patient upon whom I operated for ruptured perineum nine days ago, and found the result perfect. While the case is fresh in my mind, I have considered a short article on this operation not out of place. This subject has been so freely discussed in the journals lately that I almost hesitate to adding to the discussion the conclusions from my limited experience. The fact that I have succeeded in securing admirable results by what I believe to be a new method of treatment, is the only apology I have to offer for this short article.

In the case in question the laceration was recent; the patient having been confined on the 9th of October of her first child. She was 30 years old, and her perineum was so rigid that I could not prevent a slight rupture. In regard to the case of the perineum, I have lately come to think the obstetrician should carefully watch the progress of the second stage of labor, exposing the parts to view. I have long since abandoned the practice of supporting the perineum, but I believe it is absolutely necessary to control the head of the child, and to direct the progress of labor so as to prevent a rupture of the parts. This can be done most successfully by bringing the occiput or chin, as the case may be, well forward under the pubic arch, and by holding the child's head back by well directed pressure until the perineum is slowly and successfully passed. If a perineum can be saved, I think this will do it. As an adjunct to the method, I invariably pour warm olive oil or vaseline into the vagina, between the pains, when the head is pressing against the perineum.

After the third stage of labor is completed, a careful examination should be made by thoroughly cleansing away all blood with a warm water antiseptic solution. For this purpose I prefer boracic acid. If, then, any rupture be detected, no matter how small it may be, it should be stitched up immediately; for in this, as in any other wound, the sooner the parts are nicely adjusted the better.

The following is the method I am now using, and I am pleased to say with perfect results: In a recent rupture, with the parts so much swollen that if the thighs are pressed together the perineum bulges forward, the deeper parts are firmly pressed together and the ruptured portion is really in good position to heal. This would, no doubt, often take place did not a clot of blood now and then sweep through, having irritating discharges in contact with the torn surfaces. But, bearing in mind the fact that this is very likely to happen, I treat these ruptures just as I would any other wound, by first irrigating the part with some antiseptic lotion; then, as soon as all bleeding has ceased, I stitch it up very carefully so that there is no gaping between the stitches and no point exposed to the discharges which must necessarily pass through the outlet of the vagina. I never insert deep sutures, and do not consider them necessary in cases of recent rupture. After washing out the vagina with a syringe, using hot water and boracic acid, I pass a pledget of raw cotton tied to a string into the vagina, carrying it well above the ruptured part. I use raw cotton because it will not absorb the blood or allow it to pass. I now irrigate the wound with the hot boracic acid solution until all hemorrhage ceases, and then adjust the mucous membrane nicely and stitch it carefully with silk thread, using an ordinary sewing needle. I next smear a little vaseline over the part, remove the cotton and wash out the vagina. This completes the operation, and the patient is afterward treated as if no rupture had taken place. I remove the stitches on the eighth or ninth day. In conclusion I may state that I always bathe the genitals of a lying-in woman, and wash out the vagina once or twice daily with a boracic acid solution and dust the parts with powdered boracic acid when ever any lesion has taken place.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 23, 1888.

The President, Laurence Johnson, M.D., in the chair.

Dr. Daniel Lewis read a memoir of the late Dr. Wesley M. Carpenter, and offered resolutions, which were adopted.

Dr. Charles McBurney then read a paper on

External Perineal Urethrotomy as a Prevention of Complications after Operations upon the Urethra,

in which he said, that for some time he had been of the opinion that urethral fever was due almost, if not quite, always to septic infection. This view was supported by the fact that sepsis occurred more frequently in operations upon those portions of the urethra in which there was least opportunity for drainage. In the anterior pendulous portion of the urethra, blood and urine found their way easily toward the meatus, while posteriorly the flow by gravity, the patient lying upon his back, was in the opposite direction, toward the bladder. The best conditions for rapid absorption of septic material coming in contact with the wound, existed after division of the urethra. The treatment of diseases of the urethra by external urethrotomy had given good results. It seemed to him that the reason for success in these cases, and in operations on the anterior portion of the urethra, was that conditions favorable for drainage existed. The following conclusions were reached: 1. For all points not more than four inches and three-fourths from the meatus, internal cutting operations are best, and drainage will be sufficiently good for safety. 2. For all points farther from the meatus than four inches and three-fourths, cutting operations are also best, but the wounds here cannot drain properly and so be safe without a perineal opening. 3. External perineal urethrotomy is indicated in all cases in which, in the deep urethra, such conditions are present as may result in hemorrhage, septicæmia, urethro-perineal abscess, or infiltration of urine.

Dr. L. Bolton Bangs was in accord with all the author had said except that he believed some cases of urethral fever had a nervous element in them.

Dr. Robert Abbe thought that absorption of urine after operation upon the urethra might sometimes be the cause of blood poisoning, but it was his belief that in nearly all cases of urethral fever from sepsis, the poison was introduced from without by the operator. The difficulty of cleansing the urethrotome was great.

Dr. F. N. Otis related some cases illustrative of his view that urethral fever was not infrequently due to a reflex nerve influence. For instance, a certain patient always had urethral fever following instrumental interference with the urethra, except when he took quinine.

Dr. McBurney, in closing the discussion, said he could see no reason for excluding the cases related by Dr. Bangs and Dr. Otis from among those of urethral fever arising from sepsis. He did not like the term urethral fever.

Reports of Clinics.

COLLEGE OF PHYSICIANS AND SURGEONS.

MEDICAL CLINIC—PROF. DELAFIELD.

Hæmophilia.

The first patient brought before the class on January 5, 1888, was a boy of 9 years who had always been well until last year, when he was taken with bleeding from the gums, following the extraction of some teeth, the hemorrhage continuing for some twenty days. He has had no hemorrhage since then until Monday last, when he bled about a gill. On being stripped to the waist several areas of extravasation into the subcutaneous tissue of the forearm were noticed. He shows some malnutrition, the so-called chicken-breast, and a slight lateral curvature. The muscles are flabby but quite well developed. The mouth is in an unhealthy condition. According to the father's account there is no disposition to bleed in the branches of the family. Prof. Delafield remarked that a slight scratch is often followed by severe and prolonged bleeding in those affected with this disease, and referred to a case in which a cut of the face was followed by a profuse hemorrhage, the blood spurting for quite a distance. That the blood has sometimes been found to contain a deficiency of fibrin, and that the disease frequently runs in families, is about all one knows of the disease.

In the treatment of this affection, we succeed best in those cases in which a correction is needed. In this case the treat-

ment has reference to the improvement of the general health. With this object we will give him small doses of arsenic ($\frac{1}{80}$ of a grain), combined with ipecac. ($\frac{1}{6}$ grain), and iron (gr. ij) in pill form; one pill to be taken three times a day after meals; and give him also cod-liver oil in teaspoonful doses, gradually increasing the quantity to a tablespoonful three times a day. He must take no tea, no coffee, no pastry or sweetmeats, but plenty of bread and butter, meat and fresh vegetables. As regards mental strain we must restrict his school hours. He needs play, not study. To improve the condition of the gums he must brush his teeth twice a day with a boracic acid solution; and as for the ulcerated teeth it would be advisable to wait for their extraction until his condition is much more improved.

Stomachic Vertigo.

The patient, a rather stout man, complained of dizziness and a feeling of pricking and of contraction in the hands, two months ago. These attacks of vertigo were sometimes so severe that he would often have fallen if he had not grasped some object. Prof. Delafield remarked that it was not so very unusual for patients affected with vertigo to experience these peculiar subjective feelings. This patient had been placed on teaspoonful doses of Carlsbad salts in a tumbler of warm water every morning, and has steadily improved. He still suffers from slight digestive disturbances, yet his vertigo and the peculiar sensations in his hands have now entirely left him. Prof. Delafield said that he would now gradually diminish the amount of the Carlsbad salts until the patient takes nothing but his tumbler of warm water in the morning.

Malaria.

This patient's illness dates back fourteen months, when she was attacked with a pain in her left side, and on first awaking in the morning, difficulty of breathing, which was somewhat relieved on getting up and walking about. Since then she has had fevers nightly and a cough, which latter came on about a month later. The cough, though still continuing, has diminished greatly in frequency and severity. Since her illness she has lost flesh and strength. The physical examination yielded the following signs: Resonance and breathing good at both apices; heart's action rapid, but regular; radial pulse 120; no murmur.

"Gentlemen," said Dr. Delafield, "this patient is 43 years of age. Fourteen months ago she was attacked, when she awoke in the morning, with a pain in the left side, in the region of the heart, which became better after she had walked about a little. With this she had shortness of breath. Every evening she feels hot and feverish. After the lapse of a month the pain in her side ceased. At this time she began to cough, and with this cough she has had mucous expectoration, which has been at times stained with a little blood. The fever still continues nightly, and she has lost flesh. Her appetite is not good, but there is no nausea, and she is afflicted with habitual constipation. She does not look so bad, and the physical examination shows a good condition of both lungs. The pulse is rapid, but regular, and there is no murmur. What is the matter with her?"

If the disease is chronic miliary tuberculosis it is not sufficiently advanced to give any physical signs. And as far as malaria with a chronic bronchitis is concerned, if it is that, it must be an irregular form. Of the two I am inclined to think it an irregular form of malaria. The treatment, however, will show, although these forms of malaria are difficult of treatment. We shall give her, then, two grains of quinine three times a day, after meals, with two grains of antifebrin in capsules, followed by twenty drops of dilute hydrochloric acid in water. The constipation should be relieved, and for that purpose two teaspoonfuls of Carlsbad salts before breakfast, in a tumblerful of water, will be ordered. Though the fever does not leave immediately, these patients will at least improve, eat better and feel better generally.

Broncho-Pneumonia.

This patient has been sick but three or four days. He is taken ill every winter, at about the same time of the year (January), with an attack like the present one. When the attack comes on, he has a feeling of pain and "eating" in his left side. On going to bed his cough is so severe that he is compelled to sit up all night, and it is accompanied with cold sweats and fever, and shortness of breath. He has no headache, and his bowels are regular; the tongue is coated, the appetite lost. He is a large, muscular man, with a good, well-formed chest. The resonance over his chest, however, is not good; the quality is changed, especially over the left and right upper sides; it is not pulmonary in character. Auscultation reveals a prolonged expiration, sonorous and sibilant breathing; sibilant râles in the lower part of the chest, and something like friction sounds

are present. The heart's action is regular, and there is no murmur. Behind, a few sub-crepitant râles are detected; the breathing is not so distinct. There is no difference in the vocal fremitus.

"The patient is 22 years of age, and robust. Every winter he has attacks which last about two weeks. The pulse is 100, temperature 100°. Percussion reveals an emphysema, and he has attacks of acute bronchitis with his moderate amount of emphysema. Why should this man be so sick; more sick than is to be expected by his symptoms or signs, or from his looks? To account for his condition it is necessary to look further. The rule is, to expect to find a broncho-pneumonia. You may not get the physical signs of this disease, and these signs are not here. We will put dry cups all over his chest, every day for three or four days, and later we will give him ipecac and quinine. Now we will give him a preparation with opium and send him home."

GENITO-URINARY CLINIC—PROF. OTIS.

Retention of Urine.

At his clinic held on January 5, 1888, Prof. Otis remarked:

At our last lecture we considered some of the causes giving rise to the retention of urine. To-day we will continue this subject. Gonorrhœa is followed by various accidents, the most important of which is a deposit of plastic matter in and around the mucous membrane in the sub-mucous areolar tissue, followed by its consolidation and resulting in the contraction of the calibre of the urethra Sooner or later we have following this progressive narrowing of the canal a retention of the urine. In retention from prostatic trouble, I showed you how to pass instruments, and also the embarrassments with which the surgeon was likely to meet. As, however, enlargement of the prostate is frequently met with in old people, I think you should be perfectly familiar with the methods of examination, onset of symptoms, etc., and shall therefore limit my remarks to this subject to-day.

We have late in life, in a considerable proportion of men, difficulty in urination. This difficulty is met with in about one in fifteen or twenty; in a lesser proportion the difficulty is more severe, and yet may not call for interference; but in a certain proportion of all old men, and those over 55, the difficulty is met with to such a degree as to call for instrumental interference. The first thing that is noticed is sometimes a little frequency in urination, which attracts the attention of old men more than anything else. He may rise at first perhaps but two or three times. Going on with these symptoms for a year or two, he finds at last that he cannot urinate at all. Then his physician is called, who will at once suspect the trouble. True, the difficulty may arise from a stricture of the urethra. The first thing to be done in these cases is to examine the prostate per rectum. We have here a patient who might give us some new symptoms. His age is about 67, and he has had this difficulty seven or eight years. In patients 55 or over, with difficulty of urination, you must look for prostatic trouble. This patient has had to get up at night to urinate. He says he has never had gonorrhœa, but the urethra had discharged a little.

Prof. Otis here mentioned several cases in his practice, in which the patients, when asked, denied all knowledge of ever having had gonorrhœa or any other disease, and cautioned the class to ascertain this fact if possible, as it was sometimes important to know.

Later, this patient was obliged to get up a little oftener, until finally the flow stopped altogether. Upon close questioning it was ascertained that the retention occurred after drinking rather freely of beer. This excessive indulgence in drinking is often followed by a sudden stoppage of urine, and is due to either an overdistention of the bladder or to a spasm of the urethra. The urine becoming changed in character, irritates the parts, which in consequence become more sensitive, and finally blunt reflex action. This condition, giving rise to inflammatory swelling and thickening, is followed by retention.

The patient sending for a physician then, the urine was drawn off. Early detection and relief of this retention is important, for a few hours even may damage the structure of the bladder.

Dr. Otis here referred to the case of a patient who went to bed at night after a carousal, and found, the morning following, that he could not urinate. This result, according to Dr. Otis, was due to an over-distention.

The distinction between cases of atony and non-atony is quite apparent. In cases of atony the urine will dribble from the catheter drop by drop; in cases of non-atony the stream can be increased at will. The amount of urine contained in the bladder varies. In some cases, especially in those who have had several attacks of inflammation, the bladder holds a pint, and in other cases a quart. In drawing off the urine, do it with considerable care, especially in those cases in which

the accumulation has taken place in twelve or twenty-four hours, or when the accumulation is large, as a fatal syncope may follow a too sudden withdrawal. A cystitis may also follow a too sudden withdrawal of the urine. Urethral fever may occur after the introduction of a catheter for the first time, and may be fatal. Be careful, therefore, in the introduction of the catheter, and after its introduction give a suppository of quinine and morphine, and order rest for the next twenty-four to thirty-six hours. If these cases were rare I would not so seriously dwell upon the subject; but they are *not* rare. In urethral fever the temperature may run up more or less rapidly to 104° or 105° F., and appear as a malaria; these cases are not so much to be feared. But when the temperature gradually runs up after the introduction of the catheter, you may look for trouble. In fatal cases of urethral fever we often find that the patient has had some kidney trouble.

Prof. Otis recommended the students to read the remarks on "Catheter Fever," by Sir Andrew Clark, as published in the *Lancet* some four years ago. He also mentioned the case of a man who was subject to slight attacks of retention, and who referred such attacks to hemorrhoids, from which he was at times a sufferer. This man positively refused to see a physician about his trouble, even at the strong solicitation of his wife and son. He was taken with an attack just prior to his going upon a fishing excursion, but again refused to see a physician, and moreover, insisted upon making the trip. A few days thereafter, however, his suffering became so severe that he at last consented to see a physician upon his arrival at Quebec. The delay, however, was fatal, as he died on his way to Quebec, eight days after leaving home.

In drawing off the urine, then, never allow the bladder to be completely emptied, especially when it is greatly distended, but draw off just enough to relieve the distended organ and the urgent symptoms—about a pint is generally sufficient—and immediately teach your patient to draw off his own water. If the urine be decomposed, antiseptics may be necessary. In that case draw off about half a pint more, and supply its place with a saturated boracic acid solution. In five or six hours repeat the experiment, and thus *gradually* empty the bladder.

The patient, whose presence was the occasion of these remarks, upon rectal examination was found to have a bilobed prostate of the size of a good sized lemon.

Periscope.

Ophthalmia of New-born Children.

In the January number of the *Medical Chronicle* is published a translation of an essay by Dr. P. H. Mules, Surgeon to the Manchester Eye Hospital, on ophthalmia neonatorum, which essay was awarded the prize by the "Parisian Society for the Protection of Infant Life." After giving some interesting statistics which show that the disease is decreasing in frequency, the author defines the disease in question as "a blennorrhœal disease of the palpebral conjunctiva of a new-born or comparatively new-born child." The period of incubation is stated to be about fifty hours, occasionally much less, varying with the potency of the infecting material. When infection is prolonged to three or four days, the reason is doubtless the feeble infecting power of the material, or unusual resistance on the part of the conjunctiva. If it occurs after the fifth day, it may be accepted as positive proof that secondary inoculation has taken place.

Primary conjunctival inoculation takes place by one of the following methods:

1. In utero with a face presentation, the obstetrician transmitting the infection on his finger during examination. Should the birth be delayed, it is conceivable that the infant might be born with the disease developed. 2. By the application of instruments to expedite birth, the eyelids being accidentally opened by their use; a more probable mode of infection than the preceding. 3. By the retention of contagious muco-pus upon the child's eyelids after birth, and its subsequent inoculation by the natural movements of hands, eyelids, etc., the use of a dirty sponge, or careless handling on the part of the nurse at the first washing. 4. By the direct introduction of contagious muco-pus into the eyes by the edge of the perineum.

Secondary inoculation may occur through one of the following methods:

1. By not wiping out the eyes of the child at birth. 2. By using unclean linen or other material for the purpose of cleansing the eyes. 3. By using the same water for the head and face that has been used for the body and limbs. 4. By neglecting the use of a disinfectant to the child's eyes when vaginal discharge is known to have been present in the mother before the birth. 5. By using the same sponge to cleanse the face of the infant that has been used to the maternal passages. N.B.—The risk of inoculation is enormously increased by neglecting to re-

move infected lochia by syringing. 6. By not washing the hands after adjusting and washing the mother before washing and dressing the child. 7. By using the same water, cleansing material, or sponge to a healthy infant that has been used to one affected with ophthalmia neonatorum. 8. By the fingers of the mother, if suffering from vaginitis. 9. By overcrowding, thus favoring extension of the disease. 10. By want of isolation, the healthy and diseased being allowed to mix indiscriminately together.

The treatment, which the author divides into preventive and curative, and gives *in extenso*, may be summed up by saying that all cases of vaginal discharge should be cured before labor begins by means of suitable local applications; that the vagina should be irrigated, during the second stage of labor, with a solution of bichloride of mercury (1–2000); and the utmost cleanliness should be used in washing the child, and the greatest care in protecting its eyes from all irritants, including light and draughts of air. When the disease is once developed, Dr. Mules strongly recommends Von Graefe's plan of treatment, and says:

The mother or nurse should first wash the eyes in warm water to remove the secretion and free the lids. The surgeon should be seated in a convenient chair, with a folded towel across his knees, and with medical appliances within reach of his hand. These appliances are: (1) A plentiful supply of pieces of clean rag; (2) Solutions of argenti. nit., 5 gr. to 1 oz. and 10 gr. to 1 oz.; (3) Vessel of clean water; (4) Two camel-hair pencils to apply the solutions and wash the excess of fluid away; (5) A bottle of eserine, 5 gr. to 1 oz., and dropper; (6) Lid elevators. He then receives the head between his knees, yet supported by the towel. The nurse, tucking the child's legs under her left arm, supports the body on her raised knee, holds the child's hand with one hand, and has the other at liberty to assist the surgeon. The surgeon first proceeds to examine the condition of the cornea by gently raising the upper lid with his finger; if there be any difficulty in this manœuvre he uses an elevator. A bent hair pin often answers admirably. He next everts the lids, wipes them dry, paints them with the silver solution of the required strength, taking special care to get to the *back folds of the conjunctiva*, and, washing off the excess of solution with clean water, carefully replaces the lids by drawing them downwards and away from the globe. This process is repeated by the surgeon every morning until the disease is arrested, his object being to produce a slight eschar, which either destroys the micro-organisms or prevents their multiplication. The effect lasts about twelve hours. In severe cases the solution can be reapplied at night. However careful the surgeon may be, his efforts are of little avail unless he be ably seconded by the nurse. Her duties are to prevent the recollection of pus by constantly opening the lids and wiping the matter away with clean rags; to wash the conjunctivæ with a weak alum or boracic acid solution, 3 gr. to 1 oz.; to anoint the lid margin with cerate to prevent adherence, and to combat the feverish restlessness by fresh air and careful attention to diet.

For the treatment of the complications of ophthalmia neonatorum, we refer our readers to the original paper.

The Influence of Naphthalin upon the Eye.

Dor, Panas and others have observed a series of interesting changes in the eyes of rabbits after the animals have been fed with naphthalin. E. Magnus has repeated these experiments, and has recorded the results of his observations in the *Therapeutische Monatshefte*, No. 10, 1887. From an abstract of this paper in the *Centralblatt f. d. med. Wissensch.*, Dec. 24, 1887, we learn that Magnus gave the animals from 7½ to 22½ grains of naphthalin a day. After some time there were found in the retina, scattered over the whole eye ground, numerous glistening, white specs, and also large yellowish white plaques, which were particularly thick at the optic nerve. At the optic nerve, likewise, appeared small whitish specs, which soon filled up the excavation about the optic nerve, which is so characteristic in rabbits. Also in the vitreous there appeared, but only in individual instances, single clear, brilliant opacities, like crystals of cholesterine. In the lens were found at first shadowy streaks, then there developed opacities, which formed first on the posterior surface of the lens, in the form of spider's webs. These increased in size with striking rapidity, so that in a short time the entire posterior surface of the lens seemed totally opaque. Radiating streaks ran from the posterior to the anterior surface, and finally developed on the anterior surface of the lens into an opacity which was analogous to that on the posterior surface. The nucleus and the perinuclear layers always remained free. The cataract at times also appeared first, and therefore could not be due to an affection of the retina, but must be caused by the direct action of the naphthalin alone. In the author's opinion the naph-

thalin causes a chemical combination of the nutritive fluids of the lens, which excite a process in the lens similar to inflammation. Besides this, parenchymatous nephritis occurred in all the animals.

Trephining for Meningeal Hemorrhage.

The *Lancet*, December 24, 1887, states that a woman, 26 years old, was admitted in a semi-comatose condition to St. Thomas' Hospital, under the care of Mr. Croft, about midnight, on December 11. She was supposed to have been knocked down and kicked by a horse. There was a scalp wound, not leading down to bone, behind and below the left parietal eminence, and no evidence of fracture. During the night she passed into a state of absolute coma, and in the morning had complete paralysis of the right arm and leg, but not of the face. Mr Croft trephined in the situation of the wound, and removed about two ounces and a half of somewhat granular clot, which was spread out for some distance between the dura mater and the bone. The hemorrhage was from some vessels in the dura mater (probably posterior branches of the middle meningeal), and could only be arrested by means of pressure. About six hours later the power of movement returned in the right side, and her condition gradually improved. She spoke for the first time after the injury on the 13th. Although not yet recovered, she is still restless at times and impatient of control; there is no paralysis, the wound is quite aseptic and healing, and the improvement continuous. A severe contusion of the groin was, however, followed by sloughing and cellulitis, for which incisions were required.

Poisoning with Corrosive Sublimate.

At a recent meeting of the Berlin Medical Society (*Deutsche med. Wochenschr.*, Dec. 1, 1887), Prof. Virchow demonstrated preparations from thirteen fatal cases of corrosive sublimate poisoning. In all of the cases solutions of the bichloride of mercury had been used externally in various amounts, and in all there were intestinal lesions, which Virchow was scarcely able to distinguish from those of true diphtheritic dysentery. Two of the most severe cases were those of puerperal women, whose vaginas had been washed out with solutions of bichloride in amounts not stated. Another case, in which only the early stage of inflammation of the intestines was present, was that of a man under treatment with the bichloride of mercury for syphilis.

The localization and anatomical features of all the cases were precisely those of dysentery. To offset the not unreasonable doubt that such processes could originate by means of the circulation—for in no case was the mercury introduced directly into the intestine—Virchow referred to early experiments of Liebreich, who had produced similar lesions in rabbits by poisoning with corrosive sublimate. In one of Virchow's cases mercury could be found in the affected intestine, and in the hemorrhagic spots in the latter were colonies of micrococci. It appeared to Virchow as if the sublimate had caused an intense irritation, which so changed the tissues that they presented favorable conditions to the bacteria in the intestines to settle in them.

In the discussion which followed, Senator mentioned a case in which internal use of bichloride caused remarkable changes in the lower bowel, while the stomach and small intestines were but little affected. This favored the theory of a circulatory origin of the process.

In these cases the amount and concentration of the solutions used are not given. It may not be superfluous to call attention here to the fact that sublimate poisoning does not depend at all on these factors. In Breisky's wards in the Vienna General Hospital, bichloride has given place to carbolic acid as a vaginal douche, five cases of intoxication having followed the use of 1 to 4000 solution in the other obstetric clinics in the same institution, and diarrhœas of more or less severity are common among the assistants and midwives who use a 1 to 2000 solution on the hands.

On the Limitations of the So-called "Wier-Mitchell" Treatment.

In the *Lancet*, January 7, 1888, Professor W. S. Playfair, who was the first to advocate the Wier Mitchell treatment in England, and who speaks of it as "the greatest advance of which practical medicine can boast within the last quarter of a century," publishes a communication, in which he endeavors to state the limitations of this method of treatment, and the precautions which should be taken in the selection of cases in which it is to be applied.

1. In the first place he lays down the rule, which he thinks is subject possibly to a few rare exceptions, that it is unsuited to any form of organic disease. Such a disease is locomotor ataxia. He admits that there are cases of obscure spinal disease in which it is almost impossible to tell whether the disease is functional or organic, and will

even go so far as to say that there are some cases of this kind whose nature can only be solved by submitting them to the test of this treatment. He advises that the practitioner, when in doubt, should consult a specialist in nervous diseases before undertaking the treatment.

2. In the second place, care should be taken never to apply this treatment to any marked case of mental disease. He thinks this method has often been attempted in cases of pronounced melancholia and other types of chronic insanity, in which it cannot possibly do any good, and in which it may do much harm. Strong pressure is often brought to bear by relatives and friends to have a case pronounced "hysterical," because they cannot bring themselves to face the fact that it is mental.

3. In the third place, he strongly urges every one contemplating the treatment of a case in this way, either to do it thoroughly and well, or not to do it at all. He thinks that many hopeful cases have been spoiled because the practitioner tries the method "in a modified way," the modification generally consisting in treating the patient in her own house, or in admitting the visits of friends, or in allowing the patient to get up and go out during treatment. Increasing experience has convinced him that thoroughness and completeness are absolutely essential, and should be considered a *sine qua non*. If they are neglected, failure may most certainly be predicted.

The Treatment of Laryngeal Phthisis.

At the meeting of Leeds and West Riding Medico-Chirurgical Society, Dec. 2, 1887, Dr. Ernest Jacob gave a *résumé* (*Lancet*, Jan. 7, 1888) of the methods in use among laryngologists for the treatment of tubercular disease of the larynx. He spoke of the difficulty of diagnosis, in the earlier stages, between a simple catarrhal condition capable of cure and the severer form in which tubercular infiltration and ulceration were found. Cases had been recorded in which the laryngeal affection was primary, and the lungs not at all affected; but in most cases the pulmonary lesions could be detected first. He had been in the habit of suspecting tuberculosis in all cases of catarrh which did not yield to treatment. In the early stages mineral astringents, especially iron, were of use; but in the later stages he strongly recommended insufflations of iodoform, iodol, and boracic acid, with or without one-quarter or one-sixth of a grain of morphia, according to circumstances. In the distressing dysphagia which formed so prominent a symptom in later stages, relief to pain could be given by insufflation of morphia mixed with starch shortly before a meal, or a spray of cocaine; the latter, however, should be given with an apparatus reaching nearly to the entrance of the larynx, as otherwise most of the drug was wasted on the pharynx. He had not found lactic acid of much use, and thought tracheotomy should be deferred as late as possible.

The Question of the Infectiousness of Tertiary Syphilis.

Dr. Maximilian V. Zeissl says in the *Intern. klin. Rundschau* that the following points may be made against the inoculability and transmissibility of the products of tertiary syphilis: (1) Patients with tertiary syphilis as a rule beget healthy children; (2) the secretion of a disintegrated initial lesion and the products of the papular stage of syphilis produces a re-infection of syphilis in those affected with gummata; (3) inoculations with the secretion of gummata are never successful.

In favor of the infectiousness of tertiary syphilis are the following points: (1) It has been proved by several authors, that tertiary syphilis is transmissible, although this occurs with extreme rarity; it probably depends upon the length of time which has elapsed since the primary affection of the parents. On the other hand, it is not absolutely necessary that syphilitic parents should beget syphilitic children, for it has been proved that even parents with secondary syphilis may beget healthy children. (2) There have been hitherto but very few cases of re-infection of syphilis in persons with tertiary syphilis, and even these few are open to doubt, as in them the course of the syphilis acquired for the second time was quite abnormal. (3) Inoculations with the secretion of tertiary syphilitic products are up to the present time but few, and negative results are never demonstrative; this is seen from the fact that even inoculations with the secretion of primary and secondary syphilitic products are frequently unsuccessful.

In addition to the points just made, the author adds that an additional fact in favor of the infectiousness of the tertiary syphilitic products, is that they have the same histological structure as the papule and the chancre. The positive proof of the existence of syphilis bacilli will also throw light upon this question. The question cannot yet be decided.—*Deutsche Medizinal-Zeitung*, December 15, 1887.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record. 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

DRINKING WATER AND TYPHOID FEVER.

The relation of drinking water to the production of typhoid fever, is one of the most important subjects which can engage the attention of physicians and sanitarians. It is commonly believed, and with much show of reason, that typhoid fever is caused by the ingestion of a poision of a chemical or of a biological character—a virus or a germ. This belief is, we say, plausible, and yet it is not, so far, placed beyond a reasonable doubt. There are authors whose study of cases occurring under their own observation, and of others reported by intelligent and conscientious observers, lead them to the belief that typhoid fever is an auto-intoxication due to the putrefaction of ingesta in themselves originally innocent—what has been aptly termed a "fecal intoxication."

However this may be, there can be no denial of the fact that many cases of typhoid fever seem to be explicable upon the former theory, namely, that they are caused by the ingestion of a definite poison or of a specific germ. Furthermore, there is sufficient reason for believing that the poison or germ is usually introduced into the human body in milk or water; and that when it is introduced in milk, its presence is to be attributed to the fact that the milk has received an admixture of polluted water. Thus, in the end, it is the water which is suspected, and it becomes a very serious question, whether or not drinking water is a usual vehicle for the contagion of typhoid fever.

Unfortunately for the cause of science, and for the good of humanity, this question cannot be answered positively at the present time. As has already been intimated, there is much to support an answer in the affirmative. A recent discussion at the Society of Public Medicine and of Professional Hygiene, of Paris, indicates the uncertainties which surround this question, and at the same time shows that the general drift of medical opinion is toward the conviction that an impure drinking water is a frequent cause of epidemics of typhoid fever. We have had our own experiences in America, in which well-studied local epidemics have been traced with seeming reason to the pollution of streams or of wells, with the excreta of typhoid fever; and others in which they have been attributed to impurities in drinking water which were not of a demonstrable specific character. The former source of danger need not be dilated on; the latter demands the most earnest thought from all who are interested in preventive medicine.

So far as we know, no connection has been traced, logically and incontrovertibly, between the water supply of any large city in America and the prevalence of typhoid fever. A vigorous attempt has been made to do this in the case of Philadelphia; but, although this attempt has engaged the co-operation of a weathy corporation, which had every reason to demonstrate the evil character of the drinking water of this city, the attempt has so far utterly failed.

In Europe the case is different. In one city, at least, the experience of recent years indicates that an impure river water may have been chargeable with a considerable proportion of the cases of typhoid fever occurring there. This city is Vienna, where the almost total abandonment of the Danube, as a source

of water supply, and the introduction of water from a distance and from an elevation considerably higher than that of the city, has been followed by a notable decrease in the number of cases of typhoid fever. This evidence—although it is of a negative sort, it must be remembered—is very strong; and it certainly makes it reasonable to assert that the use of the water of the Danube was formerly the cause of many cases of typhoid fever in Vienna.

An attempt has been made to show that the use of the water from the Seine has had a similar result in Paris. But this is not so clearly established. The most that can be said in regard to it is, that there is fairly good evidence that it is true.

We are not aware that any other deductions, on so large a scale, have been made for other civilized cities; and we are of the opinion that the question of the relation of the drinking water of large cities to the production of typhoid fever is not yet definitely settled. The most that can be said positively by those who have at heart the purity of their drinking water is, that experience shows it to be important that every effort should be made to exclude the possibility of infection by this means; and that an impure water certainly facilitates, if it does not originate, the development of typhoid fever.

Such a temperate statement of the case justifies a careful investigation of any suspected source of water supply, and the adoption of any practicable measures to secure for the inhabitants of a town a water supply which is above suspicion. Such investigations, however, must be candid as well as thorough, and such measures must be adopted with no other object than the good of those for whose benefit they are proposed. Meanwhile it is of the utmost importance, as is remarked by the *Gazette Hebdomadaire*, of Paris, January 13, 1888, that epidemics of typhoid fever should be subjected to thorough scientific investigation; for it is unfortunate that uncertainty should continue in regard to the etiology and prophylaxis of a disease so common and of such grave consequences to public health.

PRESCRIBING BY DRUGGISTS.

In a recent number of the *National Druggist*, Mr. James Kennedy has an article in which he defends druggists against the charge of indiscriminate counter-prescribing, and says some things which ought to be considered, in fairness to druggists and for the good of physicians. We have no doubt that the evils of counter-prescribing are sometimes exaggerated by physicians, and that the latter sometimes expect too much of druggists, in the way of sending truant patients back to them. Nevertheless, the practice of counter prescribing is one which needs very careful watching to prevent it from being a damage not only to the income of medical men, but also to the health of the community. It seems fair enough for a druggist to say that he cannot send to a physician every one who asks him for a remedy for constipation or a cold; but this claim overlooks the most important feature of these cases, namely: that both patient and druggist assume that a correct diagnosis has been made by one or two persons, neither of whom has any training in this most difficult branch of medical science.

Fortunately for mankind, a great many of the ills to which flesh is heir tend to disappear of themselves, and many of the drugs which are prescribed over the counter do no harm, even if they do no good. But we have known a number of cases in which serious errors of diagnosis or of treatment have been made by druggists. We have known syphilis to be mistaken for gonorrhœa, and scarlatina for measles. And we have seen iodism and cinchonism pushed to a dangerous point in the misguided therapeusis of men who have assumed the *rôle* of the physician without the necessary training or experience.

Within a short time we have known of a case in which a mother diagnosticated an eruption as that of measles, and a druggist's clerk confirmed the diagnosis, and said it was not necessary to apply to a physician. After this, the mother and the druggist's clerk agreed upon a line of treatment which included sponging the child's body with alco-

hol and water, without any precautions against cold; and only good fortune saved them from a disaster, for the child had scarlet fever!

For reasons suggested by a case of this sort, we think that druggists might well fix their minds more on the risks of counter-prescribing than upon what they may regard as unreasonable demands on the part of medical men. No doubt those who compound the prescriptions of competent physicians pick up a smattering of knowledge as to the uses of medicines; but those who know by experience how delicate and how difficult a matter it sometimes is to make a correct diagnosis in regard to an apparently simple ailment, cannot regard with approval the assumption, inseparable from the practice of counter-prescribing, that a druggist is a trustworthy diagnostician.

ANTIPYRIN AS A HÆMOSTATIC.

It often happens that a drug introduced into practice for one purpose soon demonstrates its applicability to others, so that its field of usefulness is changed or enlarged as time passes. The most recent illustration of this is to be found in antipyrin, the value of which in neuralgic affections bids fair to rival its value in reducing abnormally high temperature. And now it appears in a new *rôle*.

At a meeting of the Société de Biologie, of Paris, January 7, 1888, M. A. Henocque calls attention to the fact that in December, 1884, he described a hæmostatic influence of antipyrin which he has since demonstrated more completely, and which has been confirmed by other and independent observers. His own experiments indicate that antipyrin, in powder or in solution, produces constriction of the blood-vessels when applied to them directly. This view is opposed to that of Caravias and Gley, who believed that antipyrin dilates the blood-vessels; but it seems to be proved by the experience of Hénocque.

This fact is so important that it appears worth while to describe the way in which Hénocque uses antipyrin as a hæmostatic. He employs it in powder, in solution, or incorporated in an ointment or pomade. Used in powder it is applied directly to a wound, and is covered with a dry dressing of cotton or charpie. For epistaxis the powder can be snuffed up the nose; for hemorrhage from the uterus it can be applied to the cervix or to the cavity of the uterus upon a suitable tampon. For wounds he generally uses a wash containing five per cent. of antipyrin; but for deep cavities, like the nose, he thinks a twenty per cent. solution should be used. In practice he finds it convenient to use sterilized cotton or filter paper, soaked in a strong solution of antipyrin and then dried, which can be applied to a wounded surface either dry or after soaking in boiled water.

In a case of cancerous ulceration of the breast now under his care, he has used with the best results a pomade made of one part of antipyrin with three parts of vaseline (cosmoline would serve as well) rubbed into cotton cut into small segments, to make it more coherent. This he applies to the surface; when it is to be removed he loosens it with a wash containing one per cent. of antipyrin, so as to prevent hemorrhage. He changes the dressing only twice a week, and finds that it has, in this case, put an end to suppuration and to the characteristic odor of cancer.

When it is borne in mind that antipyrin is an antiseptic, it will be seen that the fact that it has hæmostatic properties also, makes it a valuable addition to the armamentarium of the surgeon and of the general practitioner.

HUMANE EXECUTIONS.

The *New Yorker Med. Presse* for January, 1888, points a keen shaft at the endeavor which is being made in various places, and most strenuously in New York, to change the method of executing criminals condemned to death, from hanging to some other way. One of the points which our contemporary makes is that this endeavor is an attempt to make humane an utterly inhumane thing. This is very true; and we share the opinion that it is a questionable

course to try to improve on the method of execution now employed in English-speaking countries.

There is no evidence that hanging causes much suffering to its victim, and there is not a little that it does not. Other methods, such as killing with electricity, or with poison, may appeal to our sentiment, but they have disadvantages which must be strongly opposed by a calm judgment. Their most important disadvantage lies in the fact that they would deprive legal executions of one of their most important objects, namely: to deter others from committing crimes punishable with death. The very fact that a legal execution is not designed to give a criminal an easy and pleasant exit from this world has some influence upon the vicious—how much, it is hard to say. But who can tell what would be the effect of robbing the law of its terrors, and of teaching brutal men, who have no thought of another world or a future judgment—especially in an age which has refined the fear of this judgment almost to the vanishing point—that when the law demands a life for a life it will deal out to the dispenser of a bloody and cruel death, euthanasia?

No thinking man would sanction needless cruelty to one who must suffer the extreme penalty of the law; but we believe that a thinking man may well consider all the possible consequences of making legal executions wholly painless and free from horror, before he permits himself to become committed to an attitude in regard to them, justified only by reasons which, if carried to their natural conclusion, would abolish the death penalty altogether.

Certainly, in this country the law's delays and the tendency to treat condemned criminals as martyrs, which has had so many and so recent illustrations, leave little to impress brutal men with the enormity of the crime of murder; and, though hanging be a dreadful thing, we cannot see any good reason for choosing a less dreadful way of punishing those whom the limitations of human power make it necessary to visit with death for their crimes.

THE OBSTETRIC FORCEPS.

In a note in the London *Lancet*, Dec. 31, 1887, the free use of the revolver is compared with the free use of the obstetric forceps; and the statement is made that the pernicious habit of carrying a pistol reminds the writer of the observation made by old obstetric writers, that carrying forceps in the pocket very much increases the temptation to use them. This is a fact; and, although it cannot be denied that the forceps are often useful and sometimes indispensable, we believe that the use of them is likely to become a habit, unless great care can be taken to prevent this.

We know of a medical man who, in more than ten years of general practice, had the good fortune to never own a pair of obstetric forceps, and to really need them but once; on which occasion he sent for a friend and his forceps, and just before they arrived the baby was safely delivered in the natural way.

REMEDY FOR EPITHELIOMA.

In the *Deutsche med. Wochenschrift*, December 1, 1887, Dr. Bidder strongly recommends the application to carcinoma of the skin, or uterus, of a powder composed of equal parts of powdered savin and burnt alum. Its application to the skin is made by rubbing it on the new growth, upon which it will act without affecting the sound tissues. In case of epithelioma of the vaginal portion of the cervix uteri, it can be applied through a speculum and kept in place by a small tampon of cotton or wool. Used in this way, it lessens hemorrhage, diminishes fever, and relieves pain. Dr. Bidder even thinks that it might affect a cure in cases in which the disease has not made much progress.

—A meeting of the commissioners appointed to investigate and report to the Legislature the most humane and practical method for carrying into effect the sentence of death in capital cases was held at Albany, Jan. 9. The commission has received, a letter from a French mechanic who thinks the electric method to be a painful operation, and offers a device which consists of a chair, in which the condemned man sits while his spinal column is immediately broken.

Pamphlet Notices.

The Radical Treatment of Trachoma. By A. E. Prince, M.D., Wabash, Ill. From *St. Louis Courier of Medicine.* 7 pp.

Wounds, their Aseptic and Antiseptic Management. By David Prince, M.D., Jacksonville, Ill. A paper prepared for the meeting of the American Surgical Association, 1887. 16 pp.

Treatment of Chronic Suppurative Otitis Media. By Seth S. Bishop, M.D., Chicago. From the *Journal of the American Medical Association*, Dec. 3, 1887. 4 pp.

Operations for Mastoid Disease. By Seth S. Bishop, M.D., Chicago. From the *Journal of the American Medical Association*, Nov. 12, 1887. 8 pp.

Statistical Report of 5700 Cases of Ear Disease. By S. S. Bishop, M.D., Chicago. From the *Journal of the American Medical Association*, December 17, 1887. 7 pp.

Babies and their Troubles. By Charles L. Gwyn, M.D., Galveston, Texas. From the *Transactions of the Texas State Medical Association*, 1886. 8 pp.

—Dr. A. E. Prince's paper was read before the Central Illinois District Medical Society, as long ago as October 19, 1886. It contains a defense of the method adopted in 1881 by Dr. Hotz, but brought forward as a method first by Mandelstam, of Moscow, in 1883. Dr. Prince calls it "enucleation of the trachoma follicles." It is, however, an *expression*, effected by the opposed thumbs of the operator after eversion of the eyelid. Incidentally Dr. Prince recommends bromide of ethyl as an anæsthetic in short operations, and believes it to be dangerous only when used to produce prolonged anæsthesia.

—Dr. David Prince in this pamphlet describes various means for securing asepsis and antisepsis for the treatment of wounds, and describes an elaborate contrivance of his own invention for securing a room full of pure sterilized air for operations.

—In this paper Dr. Bishop warmly opposes the method of filling the external meatus with a dry antiseptic powder, in the treatment of suppurative otitis media; and he recommends cleansing the meatus with a 1 to 10,000 solution of mercuric chloride, inflating the middle ear, drying the meatus and dusting it with powdered boric acid containing half of one per cent. of mercuric chloride, or with iodoform. The method he proposes is rational, and the objections he raises to the packing method appear to be sound in theory. Other otologists, who have had a different experience from his, may not agree with him as to the dangers of packing the meatus; but if he has found it inexpedient to pack, it goes for a great deal.

—In his second paper Dr. Bishop, after some very judicious remarks in regard to the measures likely to prove useful in preventing the development of threatened mastoid periostitis, describes and advocates operative interference in cases in which inflammation of the periosteum of the mastoid process, or of the process itself has developed. His views may be regarded as somewhat radical by those who have not investigated the subject thoroughly; but we believe them to be entirely sound, and they are certainly justified by his own experience.

—Dr. Bishop's third paper was read before the Section on Otology of the Ninth International Medical Congress. It contains a useful study of the age, sex and occupation of over 5000 patients who came under his care for disease of the ear, and of the climatic conditions which existed when they presented themselves. More than half of the cases (3018) were of chronic non-suppurative inflammation of the middle ear; one-fourth were of suppurative inflammation of the middle ear. More than half the cases were those of persons employed in in-door work. Other points of interest are brought out in the author's table, which, with his reflections upon his observations are a valuable contribution to the study of otology.

—There is much of sensible suggestion in Dr. Gwyn's paper in regard to the care of new-born infants. We think it especially worthy of note that he objects to the plan of stripping the umbilical cord of Wharton's jelly—a plan which we believe is sometimes the occasion of an umbilical hernia, and which is certainly unnatural. We can also heartily endorse his caution in regard to the first bath of an infant, which might well be banished altogether from obstetrical practice or the office of the nurse. Equally judicious, in our opinion, is his objection to frequent bathing of infants. It is hard to convince refined women that their infants need not, and ought not to be bathed every day; but we believe that the daily bath is one of the most prolific causes of disturbances of digestion in infants which are attributed to everything else, and which baffle the care of mothers and the skill of physicians so long as the daily bath is administered.

We cannot dwell longer on this useful paper; but commend its contents to the attention of all who have the welfare of babies at heart. Its merits are not lessened—although its literary quality is somewhat marred—by a number of errors of spelling, which are probably attributable to the proof-reader.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*La Riforma Medica*, a medical journal formerly published every day at Naples, began in 1888 the fourth year of its existence, and removed to Rome. Each number consists of eight pages, 15x11 inches, six pages being occupied by original and selected articles, reports, etc., and two by advertisements. The subscription price is 20 lire a year for Italy, and 52 lire a year for the United States.

—The *New Yorker Medizinische Presse*, which is the only medical journal in America in the German language, begins its fifth volume in an enlarged size and improved typography. It is an admirable journal, and can be commended not only to German medical men, but also to all others who can read this language. We are glad to note that the editor promises that no "inserts" will be published in the *Presse* after the present advertising contracts expire. The *Presse* is published in large octavo, 48 pages, once a month; subscription price $2.50 a year.

—The *Cosmopolitan* presents an entertaining collection of short stories and papers of more serious character, with an increasing number of illustrations. The number for January contains an article on apparitions, by Richard A. Proctor, which will prove interesting to physicians and especially to those who are engaged in the study of mental phenomena and experiences.

—The first number ot the *Brooklyn Medical Journal*, bearing date of January, 1888, is before us. It is a handsome number, containing 88 octavo pages, and filled with most excellent material. It is a pleasure to welcome it to the ranks of medical journalism and to wish for it the success which we have no doubt it will attain. There is no reason, as its editors state, why so large a city as Brooklyn, with such abundant clinical material and such competent medical men should not have its own special medical journal; and we are glad that the field is entered by one so good as this. *Floreat!*

—The *Clinical Reporter* is a homœopathic journal, published monthly, at St. Louis, by Fowler & Co.; price, $1.00 a year. The first number, for January, 1888, consists of 24 pages, and contains the statement that it "is entitled to a place in the very front rank of homœopathic journals." This modest assertion will probably be questioned by intelligent homœopaths; and honest homœopaths will, no doubt, take some exception to its wholesale advertising and puffing of certain trade-marked medicines which are at the furthest possible remove from homœopathy. The literary quality of this first number is poor, and its inconsistency is astonishing.

Correspondence.

Release from Responsibility.

Editor Med. and Surg. Reporter:

Sir:—Please oblige an old subscriber with an answer to the following question: Can a *legal* instrument be written, which, on being signed by an adult patient with a dislocated or a fractured bone, will relieve a surgeon from responsibility for any unfortunate result which may follow, directly or indirectly, from the injury received or from the treatment which the surgeon thinks best to use in the treatment of the case?

The above question has been asked of several lawyers here, who say that an instrument cannot be made which would relieve a surgeon from responsibility, no matter how the paper was worded. I would be pleased to have your opinion on the question, as I am inclined to think such a paper could be drawn, in order to protect the surgeon from a certain class of patients who are likely to make the surgeon much trouble and expense, so long as the system of jury trial continues and unprincipled lawyers abound. Hoping to hear from you on this subject, I am Yours truly,

Jan. 25, 1888. A Subscriber.

[A patient is entitled to receive from his physician or surgeon intelligent and skilful treatment, and so long as the physician discharges his duty with fidelity, intelligence and skill, he is not responsible for the results, and needs no previous written release from his patient. If a physician or surgeon is unskilful, inattentive, ignorant or negligent, he is legally responsible for the results; and it is against public policy to permit him to be released from such responsibility. A previous written release in such case is no protection, and would be set aside. The opinion of the lawyers to whom our correspondent applied is entirely correct, and there is no way in which a physician or surgeon can escape an unjust prosecution if he happens to treat a person unprincipled enough to try this means of making money.—Editor.]

Pruritus Ani—Burns.

Editor Med. and Surg. Reporter:

Sir:—Allow me to recommend the following prescription for pruritus ani:

℞ Salicylic acid.....30 to 60 grains.
Cosmoline..... 1 ounce.
M. Sig.—Use locally whenever the itching recurs.

The first sensation from this application will be one of heat and moderate smarting, followed in from one to five minutes by a most complete sense of relief and comfort. In even old and and very obstinate cases the itching will not recur for days, and sometimes for weeks. I would respectfully suggest to my fellow readers of the Reporter to try the salicylic ointment before resorting to the actual cautery, as recommended by Mr. Mitchell Banks (see Reporter, January 21, p. 95). I could back up my recommendatory with a very respectable showing of clinical evidence. I was myself a chronic sufferer from this malady for two years, and first used the prescription on my own person.

I have long since discarded the linseed oil and lime water dressing for burns, and instead have tried to teach my patrons how to use the bicarbonate of soda. Antisepsis is just as important in the treatment of burns as of other injuries. Take from five to ten per cent. carbolized water, and bicarbonate of soda a sufficient amount. Moisten the soda to a pasty condition, and spread the carbolized soda paste thickly over the entire burned area with a knife or spatula. Next moisten layers of absorbent cotton, or of old linen or muslin, in the carbolized water, lay them over the paste dressing, and secure them with a light bandage. By this time the pain in the burn will have nearly ceased.

The bandages should be kept constantly moist with a five per cent. solution of carbolic acid in water, for two days. At the

end of this time the dressing may be gently removed and a new one applied, consisting of saturated solution of boric acid with a sufficient quantity of sub-nitrate of bismuth to make into a paste. This should be applied as was done with the soda paste, and allowed to remain untll the burn is well, unless indications of pus secretion should show through the light bandaging. In such a case the dressing may be removed, the burn cleansed, and the dressing re-applied. If this dressing becomes dry and irritates, it is to be moistened with boric acid solution.

Yours truly, G. Law, M.D.

Greeley, Colorado,
January 25, 1888.

Useful Prescriptions.

Editor Med. and Surg. Reporter:

Sir:—I would like to lay before the readers of the Reporter two prescriptions which I have used with much success. They are the same in principle as others which have been published before, but I believe them to possess some advantages over any which I have seen. They are easily prepared and keep well.

No. 1.

Take: Sulphate of strychnia.....4 grains;
Dilute phosphoric acid... 2 fluid ounces;
Fluid extract of cinchona..8 fluid ounces;
Madeira wine.....1 pint;
Simple syrup.. .....6 fluid ounces.

Dissolve the strychnia in a small quantity of the phosphoric acid in a test-tube, with the aid of heat, and then mix the various ingredients, and filter. The dose is a teaspoonful or two in a little water.

This prescription I have found useful in all cases in which a nerve tonic was indicated. In preparing it, I sometimes substitute alcohol, diluted with 25 per cent. of chloroform water, for the Madeira wine, and glycerine for the simple syrup.

No. 2.

Take: Hot water.....2 pints;
Salicylic acid.....8 ounces;
Acetate of potash.....1 pound;
Tincture of colchicum seeds. 24 fluid ounces;
Glycerine.....1 pint.
Water....enough to make 6 pints.

Dissolve the salicylic acid and acetate of potash in two pints of hot water; the other ingredients are to be then added, and the whole filtered. The dose is from one to four teaspoonfuls every four or six hours.

In chronic muscular rheumatism, I often add the fluid extract of black cohosh (snakeroot) in ten to fifteen drop doses. Both these preparations I keep always in stock, and find them very useful and handy remedies.

Yours truly, A. D. Bundy, M.D.

St. Ansgar, Iowa,
January 24, 1888.

Notes and Comments.

Reminiscences of Ricord.

Hon. Chas. Gayarre, in an address before the New Orleans Medical and Surgical Association (*New Orleans Med. and Surg. Journal*, January, 1888), gives an account of a number of physicians whom he had met in the course of a long life of partial invalidism. From this address we take the following interesting reminiscence of Ricord:

His genial manners were as enticing as his conversational powers, when he chose to exert himself. There was not much difference of age between us. He was born of French parents, in Baltimore, and rapidly rose to celebrity in the land of his ancestors. His capacity for labor was incredible, and his physical strength was equal to any fatigue. At early morn his work began. After numerous visits and after having attended the crowded hospital of which he had the charge, he would return home at 11 o'clock to breakfast, and from 12 to 6 P. M. his reception of patients lasted. At 6 precisely, the door of his office was closed. Those who had not the good fortune to see him had to take their chance on the next day. After dinner he drove rapidly to every part of the vast city where he was needed, and sometimes at 2 o'clock in the morning he was to be met at the masked ball of the Grand Opera as fresh and buoyant as if he had had nothing to do but sleep during the day. On every Sunday he denied himself to the public and went to some solitude in the environs of Paris, where he wrote what he intended to publish. He affected to be a materialist and advocated his thesis with much intellectual vigor and much apparent conviction. As I was opposed to the annihilation of my soul, I always took the opposite side of the question. An incident, however, made me doubt the sincerity of his sentiments on that subject.

As I have already said, the immense saloons of the great physician were always full from noon to six in the afternoon. The patients were admitted in turn to his presence. He was unapproachable during those hours except to suffering humanity. As a proof of his regard he had kindly exempted me from the rule. One day when I had something to communicate to him without delay, I called at the time I knew him to be engaged.

"Pierre," I said to the servant who was in attendance, "carry my card to your master. I must have access to him without being seen by the crowd of invalids who might complain of preference granted to me if I

were admitted before those who preceded me here."

He returned after a few minutes and said: "I will conduct you, according to the doctor's instructions, to his bed-chamber, which can be reached through a secret passage. There you will please to wait until I am permitted to take you to his office."

Ricord, at that time, was a bachelor, and I believe has never married. What was my astonishment, when I entered a very large bedroom, of which the walls, from the high ceilings to the floor, were covered with none but magnificent oil paintings, representing sacred subjects. At the head of the bed was a sculptured oak *prie-dieu*, on which there was a superbly illustrated copy of the Gospels that was lying open. There was a red velvet cushion to kneel on at the foot of the *prie-dieu*, surmounted by a beautifully carved ivory figure of Christ on a gilded cross. After a little while I was led to the presence of the medical philosopher, who habitually seemed to delight in being a cynical unbeliever. Guessing at what had passed in my mind, he said, with a laugh not unmixed, I thought with some embarrassment of manner, "You are surprised, are you not?"

"Certainly," I replied; "who would not? Faith! my first impression was that I had been introduced by mistake into the bed-chamber of the Archbishop of Paris."

"Well! Well! my friend," said he, in a half jocose and half serious tone; "I hear and see so many unclean things during the day that on retiring at night I like, before going to sleep, to refresh my eyes by looking round my room on holy objects."

Several times since, in my social intercourse with Ricord, who never desisted from parading his materialism, I tried to allude to what I considered a singular and secret contradiction of his openly professed doctrine, in order to obtain further light on the subject, but he always glided away from it, and, finally, I had to cease all efforts in that direction, because I saw that it was his wish to have the incident forgotten and unexplained.

Maternal Impressions.

Dr. Hartley Dixon reports, in the *Edin. Med. Journal*, November, 1887, the case of a woman who was travelling by train and had a fall. Her right eye was much bruised, and she suffered severely from it for many days. From the upper part of the left ear a piece of an angular shape was cut out. She was six and a half months pregnant at the time of this accident. In November, 1884, she was safely delivered. The child, when born, had a bruised appearance, extending over the whole lower lid and upper portion of the cheek. The left ear presented the appearance as if an angular piece had been snipped out in the same position as in that of the mother.

Experimental Studies upon the Causation of Typhoid Fever at Iron Mountain, Mich.

Dr. Victor C. Vaughan, and Frederick G. Novy, M.S., of Ann Arbor, Mich., have been investigating the cause of the outbreak of typhoid fever at Iron Mountain, Mich. From an account of their investigations in the *Medical News*, January 28, 1888, we gather that they were unsuccessful in finding any ptomaine in the flasks supplied with meat or milk, which were examined forty-seven and a half hours after they had been inoculated with the Iron Mountain or Lansing water. From a flask of meat preparation which had been inoculated with Iron Mountain water and allowed to stand seven days, however, a syrupy residue was obtained after treatment with suitable reagents. This, when injected into cats, produced fever, retching, anorexia, dilated pupils, and coryza. The symptoms lasted generally only a few hours. One animal seemed to have pain in the abdomen. One cat was killed with chloroform, and redness of the mucous membrane was found, with small ulcerations in the region of Peyer's glands. The authors remark that, if their extract contains the typhoid poison, they would expect it to produce in general the symptoms of the disease; but they would expect these symptoms to be temporary. In 1885, Brieger obtained a ptomaine from a pure culture of Eberth's bacillus, but the symptoms obtained from injecting the latter into animals were a slight flow of saliva, frequency of respiration, dilatation of the pupils, profuse diarrhœa, paralysis, and death within twenty-four to forty-eight hours. The bacilli of Eberth are described as about one-third the size of the red blood-corpuscles of man, and about three times as long as broad; though they may grow to long threads. The short rods have plainly rounded ends and very active movements. They are affected by the aniline colors less than most germs, and are best stained by methylin-blue. Birch-Hirschfeld has recently detected spores by growing the bacillus in stained cultures. Seitz and Wolfhügel have found that it grows abundantly in milk. Hochstetter found the germ in artificial seltzer water a week after its introduction. Seitz found that quinine, kairin, antipyrin, thallin, salicylic acid, and calomel in certain

proportions, arrest the growth of the germ in cultures; but that naphthalin, which seems to be a useful intestinal disinfectant in some diseases, is without effect upon the typhoid bacillus. Upon potato, the typhoid bacillus shows a characteristic but invisible growth. Kraus has declared that the ordinary water bacteria destroy the typhoid bacillus.

A chemical analysis of the Iron Mountain water shows a great excess of chlorine. The wells which supplied the infected water were from six to twenty feet deep. There is no sewer to carry off the filth, but there is a large ditch running through the village, which conveys the water from the mine to a small lake beyond the village. This ditch is used by many as an open sewer, and ice taken from the lake into which it empties supplied the village last summer.

In conclusion, the authors state that there cannot be any doubt that the epidemic at Iron Mountain is one of genuine typhoid fever. The intestinal lesions were observed in one post-mortem. Similar lesions were found in the cat; the specific germ of typhoid fever exists in the water; and the chemical poison, or ptomaine, is formed by the growth of this germ.

The Frequency of Cancer of the Larynx in Different Countries.

M. Mollière, of Lyons, says the *Lancet*, January 14, 1888, thinks that carcinoma of the larynx must be much more common in Germany and Italy than in France and England, for while he himself sees annually some 7000 surgical patients, he has never had a case suitable for extirpation of the larynx. This operation is known to be a very uncommon one in France and in England, while no less than seventy-six cases were mentioned at the Dresden Congress, and 101 operations are referred to in the Italian "Archives of Laryngology."

Enormous Nævus.

R. v. Planner reports, in the *Vierteljahrsschrift f. Dermat. und Syphilis*, 1887, p. 449, the case of a female infant, six months old, who had a nævus larger than a child's head, and including the upper half of the right thigh, the right labium majus, the perineum, and the right buttock.—*Centralblatt f. die med. Wissensch.*, Nov. 19, 1887.

Pasteur Institutes and Hydrophobia.

Dr. Geo. W. Rachel says (*N. Y. med. Presse*, Nov., 1887) that it is a very suspicious circumstance that in all the countries in which a Pasteur Institute exists, the number of cases of rabies reaches an incredible height; while in other countries, particularly in Germany, this increase is very moderate, and affects only those who can actually go to Paris to Pasteur. The opinion that rabies is nothing but a psychical disease, which has been embraced hitherto by only a small minority among physicians, is strongly supported by this fact. Later generations may look upon it as a great, though in truth an unwilling service on the part of Pasteur, that by his leadership in this direction he has contributed very largely toward undermining the belief in rabies and consigning this last remnant of superstitious error to the same limbo of forgetfulness into which sorcery and witchcraft have already fallen.

Treatment of Pruritus Senilis.

For the treatment of this obstinate affection Machiavelli recommends (*Gaz. med. Ital.*) external remedies as most efficacious. As general measures, baths medicated with sulphate of potassium, and the avoidance of all excess in diet. The patient must abstain from scratching, and when a paroxysm of itching comes on, he should dab on the pruriginous spots a one to two per cent. solution of carbolic acid in water. If papules appear and the pruritus is worse at night, cloths soaked with the same solution are to be bound on. An itching scrotum is to be worn in a suspensory bandage enveloped in absorbent cotton. In persistent itching, especially of the female genitals, repeated bathing with the following—

Carbolate of sodium	25	grammes.
Cologne water	75	"
Glycerin	100	"
Water	300	"

M.

will be useful, especially if followed by compresses soaked in the following:

Distilled water	300	grammes.
Alcohol	100	"
Hydrochlorate of cocaine	75	centigrammes.

M.

When the patient cannot resist the impulse to scratch, and does scratch unconsciously at night, the parts are to be painted with:

Ammoniate of mercury	1	gramme
Oxid of zinc	4	"
White vaseline	40	"
Cocaine	25	centigrammes.

M.

—*N. Y. Med. Journal.* Dec. 24, 1887.

Rewards for Service to the Crown Prince.

The *Med. Press and Circular*, Jan. 11, 1888, says: The attending physicians and surgeons of the Crown Prince of Germany have not been neglected by their illustrious patient during the season of "peace and good will toward all men" recently passed. For example, it is reported that Sir Morell Mackenzie has received as a present a valuable case of instruments; Herr Krause, a diamond pin; Herr Schroeter two superb Japanese vases; Herr Bergmann, twenty-four silver table ornaments; and Herr Schmidt, a gold inkstand. Apart from the intrinsic value of the gifts, it is quite possible to conceive that the possessors will treasure them as an earnest proof of the gratitude of the distinguished donor, on whose behalf their best efforts have been lately expended in order to avert distressing symptoms.

How to Clean the Hands.

Dr. P. Fürbringer, of Berlin, has published a pamphlet upon the disinfection of the surgeon's hands and finger-nails. From an abstract of this in the *Med. Press and Circular*, Jan. 11, 1888, we take the following, which the author recommends as the speediest method of cleansing the hands, consistent with security:

1. The nails are to be cleansed dry (scraped or rubbed) from all visible dirt.

2. The hands are to be thoroughly scrubbed with a brush for a minute and a half in hot water and soap, special attention being paid to the edges of the nails.

3. They are then to be washed for one minute in alcohol (not under 80 per cent.), and then, before drying,

4. They are to be put into the disinfecting solution, 2 per cent. sublimate or 2 per cent. carbolic solution, and here to be thoroughly cleansed for another minute.

He claims for this method (1) Certainty of disinfection. (2) Saving of time. (3) Saving of the hands. (4) Smaller expense in the use of the sublimate.

The William F. Jenks Memorial Prize.

The first triennial prize, of two hundred and fifty dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on "The Diagnosis and Treatment of Extra-uterine Pregnancy." The conditions annexed by the founder of this prize are, that the "prize or award must always be for some subject connected with obstetrics, or the diseases of women, or the diseases of children;" and that "the trustees, under this deed for the time being, can in their discretion publish the successful essay, or any paper written upon any subject for which they may offer a reward, provided the income in their hands may in their judgment be sufficient for that purpose, and the essay or paper be considered by them worthy of publication. If published, the distribution of said essay shall be entirely under the control of said trustees. In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Philadelphia." The prize is open for competition to the whole world, but the essay must be the production of a single person.

The essay, which must be written in the English language, or, if in foreign language, accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U. S. A., addressed to Ellwood Wilson, M.D., Chairman of the William F. Jenks Prize Committee, before January 1, 1889. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year. The committee reserves the right to make no award if no essay submitted is considered worthy of the prize.

Hæmostatic Pills.

Huchard recommends (*Revue Internationale des Sciences Médicales*):

> Aqueous extract of ergot,
> Sulphate of quinine, of each 1 drachm.
>
> Mix. Divide into 40 pills. Dose, six to ten pills a day for hæmoptysis, metrorrhagia, etc.

The Duration of Pregnancy.

In an inaugural dissertation bearing the title, "Is There a First Month of Pregnancy?" (Berlin, 1887), Sachs has endeavored to solve the question as to the time of conception in a new way. As is well known, opinions have differed heretofore as to whether impregnation occurs with the ovum of the last menstrual period or with that of the first period which is missed; or, as Leopold has suggested, from an intercurrent ovulation. The new theory, founded by Sigismund, Löwenhardt and Reichert, that it is the ovum of the first missed period which

is impregnated, though not generally accepted as correct, is nevertheless claimed by its original defender as being of universal application. If this were true, as His has already pointed out, the position of the day when the productive coitus took place would have no effect on the duration of pregnancy, since the latter begins with the first absent menstruation. Sachs has collated from the literature of this subject all cases in which a single intercourse led to pregnancy—in other words, in which the period of conception could be definitely fixed. From these he has arranged a series, according to the relation of this period to the time of the last menstruation, and has compared in this series the duration of pregnancy in the different cases, or the time elapsing between the first days of the last menstruation and the date of confinement. From the comparison it appears that in those cases in which the period of conception was near the last menstruation, the average duration of pregnancy was 277 days, while in the cases in which it was near the first missed menstruation, the duration was 293 days. Since such a difference can hardly be accidental, Sachs looks on it as proving that the later the period of conception the longer is the duration of pregnancy.

Strangulated Femoral Hernia, with Entire Absence of Local Pain.

In the *Lancet*, January 14, 1888, Mr. O. B. Shelswell reports the case of a woman, 49 years old, who applied to him on November 20, suffering from very severe abdominal pain especially on the left side and around and above the umbilicus; vomiting and constipation were also present. These symptoms had commenced on the previous day. It was learned, on inquiry, that purgatives had been employed, but with no effect on the constipation. There was a lump in the right groin, to which the patient had given no heed, as it was not painful. It was of irregular shape and felt very hard, except at the lower part; no impulse was felt on coughing. The diagnosis of hernia was aided by the history that the tumor had appeared suddenly some weeks previously. Taxis was tried, and though it did not produce pain, was without success; and on the next day, as the nausea had increased and the vomit was very offensive, Mr. Shelswell operated. The result was entirely successful. This case is interesting and instructive, as illustrating the fact that strangulated hernia may exist with entire absence of local pain.

Treatment of Warts by Internal Administration of Arsenic.

Mr. B. G. Pullin, in a communication to the *Bristol Medico-Chirurgical Journal*, December, 1887, says that during the last two years many cases of warts on the hands of children have come under his notice for treatment. He reports three cases, which, if they are to be credited, certainly show remarkable efficacy on the part of arsenic. The first case was that of a young woman of 17, who had innumerable warts on her hands, which had grown with great rapidity. Some of the largest of these had attained their growth within a week or ten days; the whole skin of the hands seemed to be filled with small growths, some not visible, but easily distinguishable to the touch. Nitric acid was applied to about one-half dozen of the largest, and she was given three minims of liquor arsenicalis, and returned in a week without the vestige of a wart. In the second case, that of a boy 8 years old, no local treatment was used, and all the warts but one had disappeared in two weeks, under two minims of the liquor arsenicalis. The remaining one was removed with the finger. The third case is similar to the second.

Philadelphia Clinical Society.

The Philadelphia Clinical Socity at its annual meeting, January 27, 1888, elected the following officers: *President*, Dr. Mary E. Allen; *First Vice-President*, Dr. Clara Marshall; *Second Vice-President*, Dr. Marie B. Werner; *Treasurer*, Dr. L. Brener Hall; *Rocording Secretary*, Dr. Mary Willits; *Reporting Secretary*, Dr. Mary Willits; *Corresponding Secretary*, Dr. Emma E. Musson; *Councillors*, Dr. Amy S. Barton, Dr. I. G. Heilman, Dr. A. Victoria Scott, Dr. Edward E. Montgomery, Dr. James B. Walker.

Northern Medical Association of Philadelphia.

At the last annual meeting of the Northern Medical Association, of Philadelphia, the following officers were elected for the year 1888: *President*, George W. Vogler, M.D.; *Vice-President*, Joseph S. Gibb, M.D.; *Recording Secretary*, Daniel Longaker, M.D.; *Reporting Secretary*, Louis J. Lautenbach; *Treasurer*, Charles P. Noble, M.D.; *Censors*, J. P. Stritmatter, M.D., to serve four years; L. Brener Hall, M.D., to serve five years.

Iodoform in Surgical Practice.

A "General Practitioner" writes to the *Peoria Medical Monthly* that he has employed iodoform with great freedom in many cases of severe injury, with extensive laceration of tissue, and the wounds have proceeded from first to last dressing without any other application whatever. He is heartily in favor of the dry dressing of wounds, and has found no agent which has so satisfactorily served this purpose as iodoform.

He says he has had four cases in which the use of iodoform has produced an irritation of the skin, which began by the formation of small, irregular elevations of the epidermis around the wound, and was accompanied by itching. In a day or two these elevations passed into vesicles containing a clear, thin, watery fluid; and, breaking down soon after their formation, this fluid kept the parts constantly wet. If the iodoform dressing be discontinued at the first appearance of the rash, and a simple soothing ointment, such as the oxide of zinc, be applied, the duration of the skin trouble is of brief duration. Care must be taken, however, to prevent the extension of the eruption to contiguous parts, also to the face and other parts of the body. He thinks the trouble is spread through the fluid contained in the vesicles, for when their watery contents flow upon adjacent parts, a fresh crop is apt to soon appear. It has in one case been transferred to the face by carelessness of the patient in not washing his hands, and in that case it spread rapidly, accompanied by great swelling and some pain. For a short time it had the appearance of erysipelas, and occasioned him no little uneasiness, but it was soon relieved by a free application of the oxide of zinc ointment. In another instance the nurse became careless about cleansing his own hands after dressing the affected part, and the rash soon appeared upon his hands, and followed its usual course.

He has only seen one case in which any constitutional affects followed the use of iodoform, and in this one the drug was used, suspended in glycerine, as an injection into the cavity of an old abscess in the inguinal region. Half a drachm of iodoform in glycerine was injected, after washing out the sac with hydrogen peroxide. After the fourth injection, the patient complained of trouble with his kidneys, scanty urine and pain in the back over the kidneys. He also complained of headache, loss of appetite, and a general malaise. The taste of the drug was quite unpleasant. A discontinuance of its use was promptly followed by an amelioration of all unpleasant symptoms. To determine the cause of the symptoms, he returned to the use of the drug in the same manner, and the same symptoms returned and continued during its use.

The author has frequently used iodoform as a local application in the treatment of erysipelas, and has found it to be better than any other application which he has used. He suspends one or two drachms of the drug in two ounces of glycerine and orders it applied frequently to the affected areas.

A Druggist Unjustly Accused.

The *Chemist and Druggist*, January 7, 1888, cites from the *Pharmaceutische Post* the following extraordinary story: In the year 1883 a chemist's assistant, named Martins, was tried at Inowrazlaw for the manslaughter of a child to whom liquid carbolic acid had been administered by mistake for some other drug, ordered at the same time by the mother of the victim. Martins had dispensed both recipes. He was found guilty and sentenced to three months' imprisonment. However, he committed suicide by drowning before the sentence was carried out. Sometime afterwards the mother of the child confessed that she had herself made the mistake of administering the carbolic acid to her infant, and then, fearing detection and punishment, had altered the labels of the two bottles so as throw the blame upon the chemist.

Effect of High License.

St. Paul *Pioneer-Press*, January 16, states that high license in Minnesota is having a very salutary effect in diminishing the amount of drinking and drunkenness in that state. It asserts that in Minnesota there are 1600 fewer saloons than a year ago; in Ohio, 2600 saloons have been closed under the tax law; in Illinois, 4000 saloons have gone. In Missouri the reduction is one-fifth. High license has cut off the very worst form of drinking. It has been impossible, hitherto, to start any new enterprise in St. Paul involving the employment of a large number of men in one building without the establishment of a saloon at the very doors. Anxious as proprietors have been to keep temptation out of the way of their men, somebody would sell or lease a lot, up would go a rough shanty, and every workingman was compelled to pass its doors on his way to and fro. In every little band of men leaving their labor there will be one or two who want to drink,

and a majority who drink occasionally, but are not bound by the habit. These latter might go on their way unharmed if there were no temptation. But the saloon is there, somebody proposes that they go in and have a drink, nobody wants to resist too earnestly, several "stand treat" according to the noble American habit, the dice are brought out, and the workingmen go away at last poorer in pocket and unsteadier in legs. This is the sort of saloon that high license wipes out. It is the worst of all saloons, because it does not minister to appetite but *creates* it.

"One further consideration," the *Pioneer-Press* says, "should be borne in mind by honest temperance men. We have never claimed that high license was a perfect panacea for all ills of the liquor traffic. We do not claim it now. We say unhesitatingly that it is the best remedy tried or known for cities. So far there are but two practical methods of dealing with the problem—prohibition and high license. On the ground of diminished drinking alone, high license is immeasurably superior in cities, while in other respects prohibition has nothing whatever to offer."

Kephir as a Food for Infants.

Kephir is the product of a special fermentation of cow's or goat's milk, analogous to koumiss. In the *Cincinnati Lancet-Clinic*, January 21, 1888, Dr. H. L. Taylor reports success from its use in the wasting diseases of children. He quotes the following conclusions as to the value of kephir from a communication by Theodoroff to the Medical Society of Würzburg, in 1886:

1. During its use the quantity of urine is increased, but only in proportion to the quantity of fluid consumed.
2. The specific gravity of the urine sinks, and also the weight of the solid matter.
3. Nitrogenous changes are checked.
4. Digestion is strengthened and stimulated in even the worst forms of dyspepsia, and the nutrition of the body is improved.
5. The gain in body weight is rapid and enormous.
6. The number of red blood corpuscles increases.

And, lastly, kephir is therefore to be regarded as one of the most valuable aids known in building up or retaining the power of the body in all conditions of great general debility.

The experiments in infant feeding at the Home are to be continued, and a second and more mature report will be made in regard to the matter.

Value of a Scrap-Book.

A man very eminent in scientific journalism was once asked by the writer what he regarded as the most valuable book of reference in his library on a certain subject. "This," he answered, and picked up a well-filled and well-indexed scrap-book, the contents of which had been accumulated by years of careful attention to the columns of the periodical literature on the subject mentioned. A trial of his plan has since proven the truth of his words. Keep files of your journals by all means, but keep a scrap-book as well. You will find that it will pay you.—*National Druggist*, Jan. 15, 1888.

Antipyrin in Hæmoptysis.

In the *Meditzinskoïe Obozreniïe*, No. 5, 1887, p. 520, Dr. M. Byvalkevitch, at the Vilna Military Hospital, states that antipyrin is an excellent remedy for pulmonary hemorrhage of every kind. This statement is based on ten cases of hæmoptysis in patients suffering from phthisis, bronchiectasis, cardiac disease, and traumatic injury of the chest. The following mixture was invariably employed by Dr. Byvalkevitch:

℞ Antipyrini.....3ss
Aq. destil.....fʒiv
Essentiæ menthæ pip.....gtt. xv
Mix. Dose—One tablespoonful every two or three hours.

In none of the cases were more than two doses of the mixture required to completely arrest hæmoptysis, even when the daily loss of blood amounted to two fluid pounds. In some of the patients, ordinary hæmostatics, such as ergot, ergotin, digitalis, atropine, and Haller's elixir, had been previously tried without effect.—*Brit. Med. Journal*, Dec. 24, 1887.

For Irritable Bladder.

Dr. W. P. Chunn writes to the *Maryland Medical Journal*, January 28, 1888, that the following prescription has been found to allay incessant desire to urinate and irritable bladder, when due to phosphatic deposits in the urine:

℞ Acidi benzoici.....3ij
Boracis.....3iij
Aquæ.....ʒxij
M. Sig.—Tablespoonful three times a day.

This mixture has, upon two occasions, acted so efficiently in what was thought to be cystitis that cystotomy was dispensed with.

NEWS.

—Dr. Thomas L. Hazzard has withdrawn from the editorial staff of the *Pittsburgh Med. Review.*

—Dr. Paul Gibier has been sent by the French government to Cuba to study the bacteriology of yellow fever.

—Dr. W. T. Councilman, who is Associate in Pathology in the Johns Hopkins University, Baltimore, has been elected to the chair of Anatomy in the same institution.

—Dr. James Hendrie Lloyd has been elected Neurologist to the Philadelphia Hospital, in place of Dr. Roberts Bartholow, resigned.

—A case of leprosy is said to have developed in Marysville, Cal. The victim is a colored barber, for twenty years a resident of that city.

—Professor Tito Vanzetti, of Padua, one of the most distinguished of Italian surgeons, died January 6, 1888, aged 78 years. He was professor of clinical surgery at the University of Padua.

—A private hospital has been established by Dr. G. Bretton Massey, at 3240 Chestnut street, Philadelphia, for the treatment of cases of nervous diseases. Patients admitted to this hospital may be under the care of the physician by whom they are sent.

—It is reported that an epidemic of pneumonia began in the neighborhood of Montpelier, Ind., about a month ago, which has caused many deaths, and many are now low with the disease. Black measles have also broken out in Keystone, a small village three miles north of Montpelier.

—Dr. J. K. Bartlett, who practiced for many years in Milwaukee, Wis., has removed from that city, and taken up his residence permanently in Berkeley, Cal. The change of residence at this period of his life was caused by the hope of benefitting the health of his family.

—If certain announcements recently made in the daily press of the country be true, the aluminium problem is rapidly nearing solution, and before the close of the year of 1888 we shall see that metal almost as cheap as German silver or the finer brasses. At 25 cents per ounce (the price at which it is now promised us), and with silver at $1.10 per ounce, aluminium is, for use in the arts and manufactures, practically nearly eighteen times cheaper than silver.

—Dr. R. A. McLain, of the Department of Animal Industry at Washington, who, with his deputies, has been engaged for the past year in stamping out pleuro-pneumonia among the cattle in Westchester county, New York, went to New Rochelle, January 19, and slaughtered about seventy registered cows on the farm of Frank J. Cazanes, who has a milk-route in the village. In and about the county several hundred head of cattle have been slaughtered to prevent the spread of the pest.

—The New York Post-Graduate School and Hospital held its annual meeting on January 18, and elected officers for the year. The treasurer's report showed the financial condition of the school to be more flourishing than ever before, the number of matriculates having this year increased over eighty-seven per cent. The hospital department has increased its space by the addition of a woman's ward, and also one for men. It is hoped that the babies' ward will soon be endowed.

—Dr. Cazeneuve, professor of chemistry and toxicology in the Lyons Faculty of Medicine and Pharmacy, met with a painful accident a few days ago. While working in his laboratory a test tube burst and several pieces of the broken glass wounded him in the face. The cornea of the right eye was perforated by one fragment, which was extracted from the anterior chamber after an iridectomy was performed. The lens has become involved and is opaque and swollen. It is feared that the eye will have to be enucleated.

—The president of the English Society for the Study of Inebriety, Dr. Norman Kerr, began a course of medical lectures on "The Disease of Inebriety and its Treatment," in the hall of the London Medical Society, on Jan. 12, 1888.

Dr. T. D. Crothers, of Hartford, Conn., delivered two lectures on the same topic, before the Albany Medical College, Jan. 24 and 25, 1888. These are the first medical lectures on inebriety, and the first efforts to present this subject in connected detail by medical men, from a purely scientific standpoint.

—The medical report on the condition of affairs at the Quarantine Station in New York Harbor, submitted by Mayor Hewitt to Governor Hill, fully vindicates the committee of Philadelphia physicians whose sharp criticism of the methods in vogue at that

place first drew attention to its condition. It shows that those physicians, far from being alarmists, did a public service worthy of the praise and thanks of New York, and of the nation. An epidemic getting a foothold in New York would cause almost incalculable damage to that city, not to speak of the personal misery and loss of life which could scarcely be confined to that port alone. Compared to that loss, the cost of properly fitting up the Quarantine Station, and of employing honest and fully competent officers to manage it, would be trifling indeed. It was a priceless service to New York to bring her authorities face to face with the actual condition of Quarantine.

—When it is a question of nerves, the power of imagination is supposed to be stronger in women than in men, but this was not shown in a recent hospital experiment. Dr. Durand, wishing to test the practical effect of mind disease, gave a hundred patients a dose of sweetened water. Fifteen minutes after, entering apparently in great excitement, he announced that he had, by mistake, given a powerful emetic, and preparations must be made accordingly. Eighty out of the hundred patients became thoroughly ill, and exhibited the usual result of an emetic; twenty were unaffected. The curious part of it is that, with very few exceptions, the eighty "emeticised" subjects were men, while the strong-nerved few, who were not to be caught with chaff, were women.

—At the last meeting of the botanical section of the Biological Society in Washington, an interesting paper was read by Professor F. H. Knowlton on the obstruction of sewers by roots of trees. A map of fibrous roots was exhibited, which was taken from an obstructed sewer in that city by Mr. Burns, of the Geological Survey. The distance to which roots sometimes penetrate, Professor Knowlton said, is remarkable. The roots of clover have been found nine feet below the surface and those of parsnips fourteen feet. Roots of the elm have been known to obstruct an acqueduct 300 feet distant, and in one instance a tile drain was filled, which was 450 feet away. Some roots absorb moisture only from free or liquid water, while others will die if placed in such water, and can obtain their supply only from hydroscopic water, or that which adheres to the particles of ordinary soil. This fact explains why the roots of certain trees are troublesome in drains and of others not.

HUMOR.

A MEDICAL STUDENT, at his examination, was asked: "If you were called to a man who had fallen into a well forty feet deep and struck his head against a stone at the bottom, what would you do?" "I would let him lie," he answered, "and have the well filled up."

"I AM SORRY," said a clergyman, "that your wife has such a heavy burden to bear." "Yes, she does—that's so," acquiesced his parishoner. "She's laid there flat on her back this seven years. Seems as if she'd get altogether worn out. I do wish she'd get well—or something."

"I WANT a surgeon at once," he said, as he hastily entered a hospital; "I've just shot three of my fingers off!" "I'm sorry, my friend," replied the superintendent, "but you'll have to grin and bear it for awhile. The surgeons are all over to the toboggan slide."—*Texas Siftings.*

A LITTLE BOY came to a druggist with a prescription for castor-oil. The druggist put it up, and the boy offered ten cents in payment. "That is not enough money," said the druggist. "There's fifteen cents' worth in that bottle." The boy thought awhile, and then answered: "I'll tell you. You drink five cents' worth, and then the money will be enough."—*Fliegende Blätter.*

A YOUNG DOCTOR, who had his eye on a banker's daughter, thought to win the favor of the father, who was his patient, by sending him a very low bill. Soon afterwards he asked the father for the daughter's hand. To his surprise the father refused, and being pressed for his reason for refusing, told the young man he could not trust his daughter to a man who had such a poor head for accounts.—*Fliegende Blätter.*

IN A LETTER to his doctor, a Liverpool man wrote: "If vaxinnation was to Prevent a person from getting this decease, and can convince me of it, You would have got my two sisters vaxinnated before this time. But I don't believe in this merracul, and have no confidence in it. If Providence whiches to lay a Person Sick in bed, no matter what decease it is—I trust in him and have confidence in him that he can Relieve them and also Prevent the decease."

A MAINE DOCTOR was called upon by a man who desired to get a prescription for whiskey. "For what purpose?" asked the doctor. "Mechanical," said the man with a countenance honest enough to look any

Judge in the country out of countenance. After writing the prescription and handing it to the man the doctor said, "For what kind of mechanical purposes do you intend to use the whiskey?" "Sawing wood. Good day, sir," was the reply.

ANOTHER LONG-FELT WANT.—Caller—Any back numbers of your magazine?

Health Journal Editor—Yes, sir. Which number do you wish?

"I do not know the date, but I saw a line in a paper to the effect that it had an article entitled 'How to lie when asleep.'"

"I know which number you want. Having trouble at night, eh?"

"I should say so. My wife says I talk in my sleep and I know from the way she acts that I tell the truth."

THE GIRARD HOUSE MEDICINE-CUP.—In the Girard House, a large hotel of Philadelphia, there is a white marble ice-water fountain, with a silver cup dangling from a chain. So many people have been taking pills, cod-liver oil, cough mixtures, and other decoctions with the help of the silver cup, that the cup got to taste like all the medicines that were mixed in it, and it smelt like a drug-store. Recently another silver cup was chained to the fountain; and over the old one hung a sign which read, "This is the medicine-cup."

THE HORSE BLEW FIRST.—A veterinary student, having been sent to administer a dose to a sick horse, was asked by his preceptor what success he met with. "None at all," he replied: "the horse bit me." The preceptor then explained that he should have put the powder into a medicine-tube, and, placing one end in the side of the horse's mouth, blow it into his throat; whereupon the student proceeded to act upon the suggestion. Returning again, he was asked what success he had this time. "None at all," he replied: "the horse blew first!"

"DOCTOR" IS A very promiscuous title in America. The preacher is a "doctor." The school principal is a "doctor." The family physician is a "doctor." The veterinary surgeon is a "doctor." The dentist is a "doctor." The manufacturer of patent medicines is a "doctor." The remover of pedal excrescences "without pain" is a "doctor." And so on. There are almost as many "doctors" in the South. But this is a free country. In Germany, under the despotism of a monarchy, this freedom is not allowed. An American dentist has just been fined in Berlin for putting "Doctor" on his cards.

OBITUARY.

ASA GRAY.

Professor Asa Gray, the veteran botanist, whose books on botany have done so much for the study of botany in the United States, died Jan. 31, 1888. He was born in Paris, Oneida County, N. Y., Nov. 18, 1810. He was educated at the Clinton Grammar School and the Fairfield Academy, and studied medicine at the College of Physicians and Surgeons of the Western District of New York, where he was graduated in 1831. He soon turned his attention to the study of botany with Dr. John Torrey. Being a clear and entertaining writer on his favorite branch, he soon became widely known, and, after declining the chair of botany in the University of Michigan, accepted the Fisher Professorship of Natural History at Harvard, a position which he held frnm 1843 to 1873, when he retired from the active duties of the office, though still retaining his connection with the school.

The honors Professor Gray received from colleges and learned societies were many; but his most enduring fame is as the author of the simple little books which tell "How Plants Grow" and "How Plants Behave," and which have planted a crop of botanists in villages and hamlets all over his native land.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Jan. 29, 1888, to Feb. 4, 1888:

Promotions.

First-Lieutenant W. W. Fisher, Assistant Surgeon, ordered to Presidio of San Francisco, Cal. S. O. 25, A. G. O., Jan. 31, 1888.

Lieutenant-Colonel Charles Page, Surgeon, to be Assistant Surgeon-General, with rank of Colonel, Nov. 17, 1887.

Major James C. McKee, Surgeon, to be Surgeon, with rank of Lieutenant-Colonel, Nov. 17, 1887.

Capt. Alfred C. Girard, Assistant Surgeon, to be Surgeon, with rank of Major, Nov. 17, 1887.

First-Lieutenant H. I. Raymond, Assistant Surgeon, ordered to Fort Bidwell, Cal.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended Feb. 4, 1888:

D. A. Carmichael, Passed Assistant Surgeon, detailed as Attending Surgeon and Acting Chief Clerk, Supervising Surgeon-General's Office, Feb. 2, 1888.

F. M. Urquhart, Passed Assistant Surgeon, granted leave of absence for twenty days on account of sickness, Feb. 3, 1888.

L. L. Williams, Assistant Surgeon, ordered to examination for promotion, Feb. 2, 1888.

ERCILDOWNE.

A Private Medical Hospital for Mental and Nervous Diseases.

Situated at Wissinoming, in the suburbs of Philadelphia, eleven miles from Broad Street Station, on the New York Division of the Pennsylvania Railroad, and within two minutes walk of the station. Commodious in structure, richly furnished, having large, airy rooms, thoroughly ventilated and heated and cheerful sun parlors front and rear. It covers twenty-nine acres of lawn and gardens, and is free from malaria. Each case receives the attention and study given to private practice, and physicians can continue as consultants in cases committed by them.

Clinical Lecture.

PULMONARY CONSUMPTION AS TREATED IN THE PHILADELPHIA POLYCLINIC.

BY THOMAS J. MAYS, M.D.,

PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC.

If it is once properly understood that, in the vast majority of cases, pulmonary consumption is a local disease, the nature of which is a low catarrhal inflammation of the alveolar spaces resulting from a want of physiological activity in the affected part, the treatment of this disease will become comparatively simplified. Strange to say, however, everything which is known to be capable of producing morbid phenomena in the human body has, one time or other, been held accountable for the causation of pulmonary phthisis; and it is needless to tell you that its treatment varied accordingly. Let us premise our remarks, therefore, by saying that it is a disease with an intense partiality for the apex of either lung; and the question which most naturally suggests itself is, why the apex is so susceptible to, and why the middle and lower portions of the lung surfaces are so free from it? Is this the result of chance, or is it a law with antecedents as plain as the phenomenon is regular? A correct solution of this important question will go a great way towards defining the true origin of this disease. While not at all wishing to be understood as offering an all-sufficient explanation of this difficulty, we are quite justified in holding that one of the most potent and direct causes for such a state of things lies in the manner in which the bronchial tubes enter and are arranged throughout the lungs. These structures conduct the air principally in a downward direction towards the base of the lungs—hence the lowest parts of the lungs expand first, then the middle, and, finally, towards the very end of inspiration the apices expand, if at all. It is our firm belief, deduced from many observations, that in most persons who —like clerks, telegraph-operators, tailors, shoemakers, etc.—lead a sedentary life, and who maintain a stooped position of their chests and shoulders, the apices never become fully inflated. Another reason why the lower parts of our lungs are inflated more than the apices is because we possess nearly one-fourth more lung surface than necessary to carry on the process of respiration; and, therefore, that part of the respiratory surface which is filled with the greatest facility, viz., the base, performs the work of the whole. Therefore both the structure and the function of our lungs conspire to diminish the activity of the apices and enhance that of the bases. We have already stated, that the chief factor in the production of pulmonary consumption is a physiological inactivity of the lung apex; and if this proposition is true, then it should follow that those persons in whom the apices are least developed should be most liable to this disease, and *vice versa.*

Not long ago we made an investigation into the nature of this problem,[1] and found that the abdominal was the original type of respiration among both sexes; that the costal type of the female developed through the influence of abdominal constriction produced by clothing; that when the female falls a victim to consumption, her costal movements are markedly diminished; and that the female is less liable to consumption than the male in

[1] An experimental inquiry into the chest movements of the Indian female.—*Therapeutic Gazette*, May, 1887.

civilized life. It can be furthermore said that, according to Waldenburg, the vital lung capacity in persons who lead a sedentary life—such as professional men, students, clerks, etc.—is smaller than those who follow an active calling—like sailors, recruits, etc.—and it is a well-known fact that the latter class is much less susceptible to this disease than the former. And, moreover, our American Indians, who are not confined on reservations, and who are free to obey their roaming instincts, are almost entirely exempt from pulmonary consumption, presumably because of the greater lung capacity which their active life entails on them.

All these facts tend to confirm the correctness of our fundamental proposition, at least this far, that increased lung capacity decreases the liability of consumption. We think, however, when this fact is coupled with the other fact, that the civilized female possesses a much smaller lung capacity than the male, and is still less liable to the disease than the male, it is quite obvious that it is not a large chest capacity, but a well developed apex capacity which insures immunity from the disease. Barring her greater apex capacity, there is no reason, so far as we are able to discern, why the female should be more exempt from consumption than the male. Indeed, everything, both in herself and in her surroundings, tends to increase her liability in this direction. She is the weaker of the two; she undergoes the enervating processes of gestation and of lactation; she leads a sedentary and inactive life; she is occupied within doors during the greatest part of her lifetime, and is therefore constantly exposed to causes which are known to produce the disease, and most of which make the male notoriously liable if he is exposed to them.

In the next place it is important to trace the pathological relation between apex inactivity and pulmonary consumption; or, in other words, we must ascertain how such a want in development prepares the apex for the onset of this disease. You are all aware that if any organ, like a muscle, for example, does not receive adequate physical exercise, it diminishes in size; its muscular elements and connective tissue framework shrink in consequence. Precisely the same thing may happen when any part of a lung is deprived of its needed exercise — that is, when it is not expanded as fully as it ought to be during the act of inspiration—the air cells begin to shrink and collapse. The shrinkage is due to a contraction of the connective tissue around the air-cells, and the small bronchial tubes, and when sufficiently pronounced it constricts the blood-vessels and interferes with the free circulation of the blood in that part of the lung, and congestion and a low state of catarrhal inflammation follow as a consequence. This whole condition is analogous to that which occurs in the acquired form of atelectasy, and we would especially commend to you the remarks of Prof. Rindfleisch on the subject Atelectasia, in his well-known work on Pathological Histology. In tracing this state of things farther, we find that the epithelial elements multiply and accumulate in the alveoli and produce what is known as infiltration. In this way one alveolus fills up after another, until a whole group, or a cluster of them, is involved. Such an accumulation of catarrhal products exerts a decided pressure on the surrounding pulmonary and bronchial capillaries, and the blood-supply and nourishment are gradually diminished and finally cut off from these infiltrated areas, which, in due course of time, become more or less isolated and circumscribed masses, which are prone to undergo a slow process of cheesy degeneration, if the morbid process continues.

Pathologically then we have to deal here with a local infiltration of, or an accumulation of catarrhal epithelium in the air cells, brought on by physiological inactivity of the affected area, which area is in the great majority of cases confined to either apex. Now, what is to be done in a therapeutic way? Clearly, there are here two very important indications. The first is to combat the local infiltration, and the second is to annihilate its cause. This is the method which has been pursued for some time in the hospital of this institution.

In regard to the first indication, we would say that we have here an inflammatory deposit differing, in principle, in no wise from a similar deposit in any other part of the body, and the dictates of common sense point out that that which is useful in the one condition is also useful in the other. We all know the inestimable value of counter irritation, and of passive motion in producing resorption of chronic inflammatory deposits in joints, muscular tissues, etc., as well as in the external surfaces; and in consonance with this view we apply hot flax-seed meal poultices, every day from morning until night, for a period of three or more weeks. In connection with the poultice we apply friction, iodine, etc. We are certain, from quite an extended experience, that these measures produce a powerful impression on the infiltration in question, and that they facilitate

resorption more markedly than any other means at our command.

In addition to the poultices, we use local or general massage, once or twice a day, as well as electricity. In these cases of constitutional lethargy these adjuvants have the happy effect of arousing the local and general cell activity, and are usually followed by an increased appetite. In connection with all these external applications—poultices, massage and electricity—we advise our patients to take plenty of fluid food, such as milk, etc. This should not be given to the extent of satiation, but at regular intervals—say half a glass or a teacupful every hour.

So much then for the principal means which we believe have the power of dispersing the infiltrated catarrhal products of the lung; and what can be done in the direction of counteracting the source of the disease? From what has already been said, it must be quite evident to you that any measure which improves the air capacity of the apices will accomplish the end in view. Among the most important measures which fulfil this indication directly are voluntary and forced breathing. The former should be practiced by taking deep and long inspirations at intervals of two hours or oftener throughout the whole day. The inspired air should be retained as long as it conveniently can be in order to give the fullest possible expansion to the whole lung surface. The latter mode of breathing consists in inhaling compressed and exhaling into rarified air, or the reverse. This method is the most important lung expander of all. It should be begun gradually—say twice a day for a week or two, then three times for one week longer, then four times, and finally allow the patient to spend most of his time in the use of this apparatus. The great difficulty here is the limited time which the compressed air is generally employed. We are convinced that the best results follow when its use is protracted.

Physical exercise is an important indirect method by which the lungs are expanded. Under these conditions more oxygen is consumed by the muscles of the body than during rest; hence more blood flows through the lungs in a given time, and a larger lung-surface is thrown into activity. Those parts of our lungs which are but rarely or never called into use now are thrown into a state of healthy expansion, and it is in this way that our whole respiratory apparatus is made to approach that condition which gives the savage, and those who pursue an active life, that freedom from consumption which we know is so common among them.

In carrying out this method of treatment, the following points should be borne in mind: first, no exercise should be carried to the extent of decided fatigue; second, whenever possible, the body and head should be erect, the shoulders thrown back, and the lungs thoroughly filled with each breath; and, third, sufficient food must be taken during the intervals. Among the most important measures to increase the lung capacity is that of pulmonary gymnastics, which should be carried out in accordance with the following directions: The arms, being used as levers, are brought as far backwards as possible, and on a level with the shoulders, during each inspiration, and brought together in front on the same level during each expiration. Another way is to bring the hands together above the head while inspiring, and gradually bring them down alongside the chest while expiring. When a deep inspiration is taken in accordance with either plan and held until the arms have gradually moved forwards or downwards, and even longer, the process of chest expansion is materially enhanced. All these movements may be facilitated by using dumb-bells or chest-weights, etc.

This, in connection with stimulant medicines and nutritious food, has been the general line of treatment pursued, both at the hospital here and in our private practice, for some time; and we commend it to your consideration, in the full belief that you will not be disappointed in its results.

—Two sons of Dr. T. A. West, recently elected City Physician of Knoxville, Tenn., and a third man, named Goodman, attacked Mr. James F. Rule, city editor of a local paper, on Sunday, January 29, as he was entering a church. The attack was made on account of a communication reflecting upon their father, which appeared in the Knoxville *Journal*. Pistols and knives were used, and one of the sons was fatally wounded. The Philadelphia *Ledger*, January 30, 1888, says that the circumstance which called out the newspaper article was the election, on Saturday, of Dr. T. A. West to be City Physician by the City Council. West is not a graduate of a medical college, and the Council had repealed an ordinance for the purpose of making him eligible. This act aroused the indignation of the regular physicians of the city and was denounced by the medical society. The article was written by a physician and contained very severe reflections upon Dr. West and the City Council.

Communications.

PRIMARY UNION OF THE AXILLA AFTER EXSECTION OF ITS CONTENTS: ILLUSTRATED BY THREE CASES.

BY J. S. WIGHT, M.D.,

PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND COLLEGE HOSPITAL.

The question of primary union of the axilla, after removal of its contents, has been one of interest to me for years. Under the ordinary methods of bringing the parts together, I have always failed to bring about such a desirable result. After studying the question from many points of view, I thought of the following plan of bringing the wound surfaces in more complete apposition: A long, curved needle is armed with an aseptic silk suture. The needle is held by a strong pair of needle forceps. The point of the needle is inserted about one-half inch from the edge of the lower posterior flap, and carried under the entire bottom of the wound of operation, so that it will come out of the upper, anterior flap, also about one-half inch from its edge. The suture is completely buried in the tissues, so that it can nowhere be seen. From the lower anterior angle of the wound, going upward and backward, I insert five or six of these long, deep sutures. In some instances I have to let the needle come out near the bottom of the wound, and then re-insert it, finishing the complete introduction. This is necessary on account of the needle being shorter than the width of the wound. Now, as to the apex of the axilla: I use a catgut suture, and bury it in the tissues of the entire bottom of the wound. The needle is pushed up through the pectoral muscles, sometimes coming out quite near the clavicle, and it is then carried back, so as to take hold of the rest of the bottom tissues of the denuded surface, and finally brought out in the anterior flap, just opposite its point of insertion. The case may require two or three of these long and deep catgut sutures. When the sutures are all in place, the cut surfaces are carefully cleaned of any blood and kept as dry as possible by the use of aseptic sponges. The suture near the lower end of the wound is tied first, and then the rest are tied in the order of their insertion toward the apex of the axilla. The catgut sutures are tied last. Then the cut surfaces are brought entirely and completely into apposition, so that the blood ceases to ooze, and so that there is no cavity left for the accumulation of blood under any circumstances. The floor of the apex of the axilla is brought into contact with its roof, and is securely held there by the catgut sutures. The edges of the flaps may now be adjusted more accurately by a few small aseptic sutures, inserted by means of a small curved needle. To illustrate the working of this plan, I will put on record the following cases:

Case I.—October 14, 1886, I saw Miss R——, of New York, with Dr. McCorkle, her physician, to consider the advisability of removing some enlarged tubercular glands of the left axilla. On the 16th of October I operated, assisted by Dr. McCorkle, Dr. W. F. Dudley giving the ether. The glands were well supplied with blood vessels, which bled freely. They were ligated with catgut as they were cut. The sutures in this case were horse-hair and catgut. The horse-hair sutures were used for the part of the wound of operation in front, and were inserted as above described, the curved needle carrying them being made to take up a layer of tissue throughout the entire surface of the denuded structures. The walls of the axilla about the apex were completely brought into apposition by two catgut sutures. The blood clots had all been carefully picked out, and the oozing surfaces had been sponged clean. There was no cavity left to contain blood, and the cut surfaces were held face to face in their whole extent, so that they could not bleed. Some cotton wool was put in the armpit, and the arm was placed by the side, and held there by a roller bandage. The fore-arm was kept in a sling. The dressings were removed at the end of six days, when complete union had taken place. The stitches were removed; the catgut had been absorbed. There had not been any oozing from the wound. In this case the axillary artery was laid bare for about two and one-half inches.

Case II.—Mrs. B——, came to my office in May, 1887, having a large cancer of the left breast. It had been "drawn out" by a cancer doctor some ten months before. It had begun to ulcerate and bleed. I operated on the 30th of May, 1887, removing a very large mass from the left clavicle downward. At the same time I removed the entire contents of the left axilla, which contained enlarged glands and other abnormal tissue. In this case I did not use ligatures: The sutures, which were made of aseptic silk, were passed, as above described, through the entire surface of the operation wound, and performed

the office of ligatures, as well. Two catgut sutures were employed to approximate the floor and the roof of the apex of the axilla. The needle penetrated both the posterior and anterior walls of the axilla, coming out just below the clavicle, and being put in again close by, so that it could be carried back to a point not far from where it started. The armpit was dusted with iodoform powder, and filled with absorbent cotton, which was kept in place by a roller bandage. There was complete primary union of the entire axilla in four or five days; and the operation wound, in so far as the breast was concerned, also healed by primary union, except a small place near the clavicle, where the flaps could not be brought together.

Case III.—Miss A. C., aged 42 years, had a cancer of her left breast, which I removed October, 1887. December 7, 1887, I excised the contents of her left axilla, the glands beginning to enlarge. The hemorrhage was quite free, so that the hemostatic forceps were required for a short time; no ligatures were applied. Several aseptic silk sutures were put in on the plan above described; and two strong catgut sutures were put through the posterior wall of the axilla, and under a thin layer of tissue up to the apex of the axilla. They were both brought out just below the clavicle, and then were put in again close by, being carried downward through the pectoral muscles, and then out near the edge of the anterior flap. The clots were picked out of the wound of operation, and the surface was kept as dry as possible from oozing blood, so that the sutures, as they were tied, brought the clean-cut surfaces in contact. The catgut sutures brought the walls of the axilla near the arm and at the apex quite close together. The sutures acted as ligatures to the entire bleeding surface, as well as to the cut arteries. There was no cavity to contain blood left, nor was there any concealed bleeding. In this case, iodoform powder was dusted over the incision, after the insertion of a few co-aptation sutures, and some absorbent cotton was put in the armpit. The arm was bandaged to the side, and the fore-arm was put in a sling. Complete primary union took place in about a week.

The points involved in this plan of operation to get primary union of the axilla after removal of diseased tissues are simple, and are not difficult to put in practice.

First. Primary union requires that the fresh surfaces be put and kept in apposition, so that the new cells of the connective tissue may grow together as they form on both sides of a wound. The sutures, as I have put them into the walls of the operation wound in the case of exsection of the contents of the axilla above described, have accomplished this purpose.

Second. The thorough arrest of the flow of blood from cut blood-vessels and from oozing fresh surfaces of operation wounds is an important condition to promote the speedy formation of scar-tissue. The sutures, as employed in the above-described cases, accomplish these two objects in a practical and satisfactory manner.

Third. The soft aseptic compress in the armpit co-operates with these subjacent sutures in keeping the entire wound surfaces in apposition, and in arresting the flow of blood from the large cut vessels and from the oozing fresh surfaces.

The results of this plan of closing the axilla, when its contents have been removed, are very gratifying to the patient and very satisfactory to the surgeon. On the one hand, the patient is up and about in a few days, and requires only one or two dressings. On the other, the patient is not unfrequently kept for weeks with a profuse discharge from the axilla, and is annoyed by daily dressings of a painful operation wound, in which there is often severe inflammation. In order to obtain primary union of the axilla, the surgeon may require a little more time than he would occupy in operating for union by granulation. But this is only a trifle compared to the time taken to dress a suppurating axilla week after week.

Of course, there are conditions of the axilla in which it would be impossible to obtain primary union. But these conditions are somewhat exceptional. It seems to me that primary union may be obtained after the greater number of exsections of the contents of the axilla. When the general health is reasonably good, and when the wound-surface can be well freshened, and when the subjacent sutures are properly put in, and when the coaptation sutures are applied, primary union of the axilla will become the rule.

—The wife of Dr. Oliver Wendell Holmes died at her residence on Beacon street, Boston, on February 6, 1888, in the 69th year of her age. Mrs. Holmes was a daughter of Judge Charles Jackson, one of the Justices of the Supreme Judicial Court of Massachusetts, who sat on the bench from 1813 until 1824. His daughter was married to Dr. Holmes in June, 1840.

PECULIAR CASE OF STRANGULATED HERNIA; OPERATION; RECOVERY.

BY MONTGOMERY LINVILLE,
NEW CASTLE, PA.

Miss Lizzie S., about 26 years of age, had occasionally noticed an enlargement in the right groin for six years. As it always disappeared in a few hours, and gave her but little pain, she failed to consult a physician until May 2, 1887, when the tumor became so large and painful that she sent for me in great haste. I found her suffering with violent cramps and vomiting, caused by a large inguinal hernia on the right side. I succeeded in reducing it in a few minutes, and as it entered the outer ring there was a distinct snapping or tearing sound, which I could not account for at the time; but later developments fully explained it. I applied a suitable truss, and warned her of the danger of neglecting to wear it. As long as she followed my advice she had no trouble. About the middle of July she became careless, and neglected to wear the truss. The result was that she again sent for me to reduce the hernia; but my efforts were not attended with the same success as on the first occasion. I gave her a hypodermic injection of morphine to relieve pain and vomiting, hoping it would relax the parts sufficiently to enable me to succeed during my next visit. But this hope was vain. I then administered chloroform, and after repeated efforts succeeded in reducing the hernia to about one-half its original size. As this gave her considerable relief, I continued the hypodermic injections of morphine, and finally succeeded in reducing the hernia on the third day. I then explained to her the importance of always wearing her truss, and stated that if she neglected to wear it, sooner or later an operation would be necessary.

But once again she disregarded my advice, and about the middle of September, 1887, while moving a wash-stand, the hernia again came down; she went to bed, and for thirty-six hours made a heroic effort to reduce the hernia herself, as she was loath to send for me on account of her disobedience. But violent cramps and vomiting forced her to do so. On visiting her, I found the hernia much larger, and more tender and painful than on the previous occasions. I should have operated at once, but my former experience made me hope that I could reduce the mass, and caused me to delay until the third day. By this time her symptoms became so alarming that I was forced to operate, assisted by Drs. James Wallace and Joseph Cooper, of New Castle. I cut down to the sac and found it firmly adherent, and that it extended from the external abdominal ring obliquely to the crest of the ilium. I succeeded with difficulty in breaking up the adhesions; but I found the neck of the sac so firmly contracted with bands of adhesions, and in such an unhealthy condition—being almost black—that it would be necessary to excise it. I proceeded to open the sac, and for a few moments was horrified with the thought that I had made a mistake and cut open the bowel, for several dark colored semi-round bodies appeared, about the size of a plum, and resembling lumps of fecal matter; but, after a more careful examination, we discovered that they were lymphatic glands in a partially broken-down condition. Immediately under the glands I found the strangulated loop of bowel, and easily pushed it up into the abdominal cavity. The sac, and especially its neck, being in a very unhealthy condition, I excised it as high up as possible. But I could not remove all of the diseased portion, as there was evidence of a local peritonitis on the right side. There was very little hemorrhage, so I inserted a drainage tube and closed the wound with deep sutures, and applied an antiseptic dressing. I had but little hope that my patient would recover. Everything was against her: the delay in operating; a delicate constitution; the diseased condition of the sac; and especially the local peritonitis. But she did gradually recover, and eventually regained perfect health.

The after treatment consisted in keeping the patient under the influence of opium. Morphia, given hypodermically, seemed to agree with her best, and I gave large doses —half a grain three or four times every twenty-four hours, for the first week. I gradually reduced the dose during the second week, and discontinued it on the fifteenth day after the operation.

The fact that we found three lymphatic glands in the hernial sac is the most interesting part of this case. The query is, how did they get there? My theory is that they became firmly adherent to the peritoneum—the hernia being of long standing—when I first reduced the mass of intestine, which was four and a half months before the operation; the glands were torn from their natural attachments, and were forced up into the abdominal cavity with the peritoneum. This supposition would account for the peculiar snapping or tearing sound which I heard on that occasion. The next time the hernia came down, the peritoneum came first, then

the glands and the bowel; thus the peritoneum formed a regular pocket for those glands. They were in this position four and a half months, slowly breaking down. For some weeks before the operation the patient complained of soreness and pain in the right side, no doubt caused by a subacute local peritonitis. I have never met with, nor heard of, a similar case. For this reason, and because my patient recovered under the most unfavorable circumstances, I have consented to write this brief history of the case.

If any of the readers of the MEDICAL AND SURGICAL REPORTER have met with a similar case or cases, I would be glad to hear from them.

TREATMENT OF LAME BACK—LUMBAGO.

BY CLARENCE G. HOLLISTER, M.D.,
MEADVILLE, PA.

About three years ago my attention was directed to the number of cases coming under my observation, in which men who were habitually exposed to all sorts of weather, and accustomed to laborous work, would come to me complaining of severe pain in the lumbar region, over the region of the kidneys, which was worse in the morning. Almost all my patients said that they did not put forth great effort on arising from bed in the morning, they could not have gotten up strength to start about their work. They all said also that the pain and lameness passed off to a certain extent as they were at work during the forenoon—although not entirely—only to recur on the following morning. Nearly all had a diagnosis ready for me, which was invariably: kidney disease. However, it seemed easy for me to diagnosticate muscular rheumatism. I had had two or three cases which had proved most stubborn, when the patient, whose case I will now describe, came to me for treatment. His case, which is a fair representation of others which followed, had extended over a period of two years, and his sufferings were so severe that I felt as if I must try some new combination of remedies.

The patient, H. E., male, about 45 years old, a cooper by trade, presenting the appearance of a hard-working and rather weak-looking man, came, almost creeping up into my office, and with his hand at his back, gradually settled down into a chair, and prefaced his request for treatment by informing me that he had suffered so with "kidney disease," or pain in his kidneys, that one-half of the time, during the past two years, he had been unable to work, and the other half he had been obliged to keep his young son at his shop to stoop for him and to hand him the necessary articles while he stood up and, with the greatest effort, made barrels to support his family. He had been under the care of many physicians, and as he was no better he was almost despairing. A careful examination did not reveal the least trouble in his kidneys, so I concluded the case was one of muscular rheumatism. In his treatment he had been given almost everything regularly known for such cases, and I therefore placed him upon the following prescription, without much confidence that it would relieve him:

℞ Potass. iodidi.....ʒss
Potas. bromidi.....ʒss
Tr. colchici sem.....fʒiss
Syr. aurantii cort.....fʒij
Aquæ..... .....q.s. ad.fʒvi
M. Sig.—One teaspoonful three or four times a day, or increased, until the bowels are slightly acted upon.

I had no great hope of success with this prescription, as I had used the same ingredients in other combinations in a number of cases before. But I sent the man home with the instructions to report in about one week. At the end of this period he did report, and was able to walk quite comfortably to my office and let himself down into a chair less cautiously than before. The improvement was marked, and I advised him to continue using the medicine. After this the patient improved so fast that when he had taken three or four bottles he declared himself well; and now, for three years, he has not been laid up for one single day, and can do as big a day's work as ever. Once every three or four months he takes, of his own motion, a small bottle of the medicine, as a sort of preventive.

This case being well known in the community, not less than eighteen or twenty cases came to me during the following two or three years, all complaining in a like manner, though some cases were not as bad as this one. All of them had lasted over a year. Among the patients who followed the cooper was a locomotive fireman, who had made up his mind to abandon his engine because the pain and lameness in the muscles of his back were so bad, paper-hangers, a blacksmith, a few farmers, etc. All but two were relieved promptly by the above combination.

There is nothing new in the use of the remedies named above, but combining them in the manner stated was new to me. The striking feature of my experience is the

fact that cases of muscular rheumatism of the lumbar region, which are usually so tedious, were promptly relieved and remain relieved up to the present time. The consequence has been that the remedy became so well known that my druggist often spoke of putting it up in bulk and handing it out *ad libitum* to all persons suffering with lumbago. But the demand for it died out with the scarcity of cases, as about all the cases of this sort of "lame back" in this neighborhood had tried the remedy and were pretty well relieved.

In closing, I will say that no simple formula ever gave me such uniformly good results as the above did in the cases for which it was indicated.

HEMORRHAGE FROM HANDS AND FEET IN AN INFANT; PELVIC CELLULITIS IN THE MOTHER.

BY E. C. HELM, M.D.,
CHICAGO, ILL.

Early in November, 1887, Mrs. K. was confined, being attended by a midwife. On December 4, I was called to see the child, being told that it was "bleeding from the hands and feet." The mother was sitting up in bed, sweating profusely, and the midwife informed me that she was "convalescing from blood poisoning." Her previous history, I learned, had been that of fever on the third day, with scanty lochia and a small flow of milk, with some abdominal pain and uneasiness. She had been better the last few days; in fact was under charge of another physician when I was called in to see her child.

The child was very pale and bloodless. On removing the blood-stained bandages from its hands and feet, I observed that the blood transuded through the skin of the palms of the hands and the soles of the feet. The blood did not readily coagulate, and was very thin, resembling bright red serum. I ordered frequent astringent washes and powders, and nourishment to be given.

In a few hours I was summoned again, and found the palmar and plantar hemorrhage had ceased, but an abundant hematemesis taking place. The blood vomited was dark and thick. A few hours after this was checked, the palmar and plantar surfaces began to bleed again. I was unable to control the hemorrhage from the stomach, and hands and feet, at the same time, for longer than a few hours, as checking it at one place invariably caused a hemorrhage at the other.

The child died in forty-eight hours. The remedies used were ergot, aromatic sulphuric acid, internal and external astringents and plenty of food, but all were of no avail. The child either bleed internally or externally the greater part of the time, but never both at once. When the hemorrhage was external, it was always from all four of the surfaces mentioned, never from one or two of them.

The mother's condition had improved and the other physician was dismissed. About the middle of December, and six weeks after delivery, I was again called, and found the patient in bed, with high fever and great pain in the region of the uterus, especially on the left side. The uterus was immovable, the *cul-de-sac* of Douglas was full and tense, but showed no signs of fluctuation. The entire pelvis, especially to the left of the uterus, was filled with the exudate. Under treatment the woman rapidly improved for three weeks, when suddenly, two hours after I had seen her, she was taken with severe pain in the region of the left ovary, and it was several days before this pain was under control. The temperature, which for the last week had been nearly normal, jumped to 104°. There never was much tympanites. A hard, sensitive mass could be felt externally, and bimanual examinations showed it to be as large as a goose's egg. It appeared to be in the folds of, or just back of, the left broad ligament, probably the latter. This grew larger for two weeks, and then the patient informed me one day "that the lump was gone." Learning that there had been no discharge of pus, I was considerably puzzled. She said the urine had been rather thick, but she had thrown it away.

Securing a sample as soon as possible, I found, under the microscope, a few pus cells. The diagnosis of rupture into the bladder was now clear. In a few days the fullness and pain returned, but they soon subsided. This process was repeated ten or a dozen times, as the opening into the bladder was doubtless small, leading to frequent refillings and evacuations of the pus cavity. From this time the pus cavity became smaller and smaller, until, three months after pus was first discovered in the urine, the microscope occasionally failed to show pus; and in another month none whatever could be found. The tumor had disappeared, the uterus regained much of its mobility, and the patient was convalescent.

This case was very interesting to me, and so I send it to the REPORTER. As the child nursed the mother while she was suffering from blood poisoning, it has been my opinion

that its sickness and death were due to the poisoned milk; although I have never heard of a case having this peculiar variety of hemorrhage.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, January 25, 1888.

The President, J. Solis-Cohen, M.D., in the chair.

Dr. Edward Martin read a paper on

Ichthyol in Surgery.

Ichthyol was first described by Schrötter, and used in the treatment of skin diseases by Unna. It is obtained as a clear yellow-brown oil by distilling bituminous matter found in the Tyrol, and containing the fossilized remains of fishes and marine animals. By the action of sulphuric acid on this distillate, and subsequent neutralization with soda or ammonia, either the sodium or ammonium sulphichthyolate is produced. The latter compound is preferred by Unna. The ammonium sulphichthyolate is a reddish-brown, clear, syrup-like liquid of burning taste and odor, soluble in water, making a clear red-brown solution, and also soluble in equal parts of alcohol and ether. The ichthyol preparations are characterized chemically by their richness in sulphur (ten per cent.), so intimately united that it can only be extracted by complete decomposition (Lartigau); they easily take up oxygen, acting as powerful reducing agents (Baumann).

Clinically, the ichthyolates are described by Unna as being powerful antiphlogistics, causing anæmia and rapid subsidence of swelling in all tissues. This antiphlogistic effect is ascribed to the drug's action on the endothelium of the blood-vessels, depriving it of oxygen in virtue of its reducing properties, and contracting the lumen of the vessels. This explanation is not perhaps entirely satisfactory, but physiological studies have not yet given us a better one. The cornifying effect of the drug on the epithelium of the rete is undoubted.

Surgically, what are the indications for the drug? Lartigau states that it is indicated in all subcutaneous and inflammatory tumefactions, œdemas, vascular dilatations, incipient furuncles, and local manifestations of rheumatism.

Elliot praises it highly in burns of the first and second degree (five per cent. solutions in water), as producing rapid subsidence of pain and inflammatory symptoms. He finds its application to obstinate varicose ulcers associated with eczema rubrum (sodium compounds, three to five per cent.) at times productive of marvellous results. In his hands it is also useful in cicatrices, and in a few cases of rheumatism and neuralgia has given immediate and marked relief from pain. Schweninger states that in rheumatism, lumbago, ischias, tic, gout, and migraine, local applications of ichthyol act more powerfully in allaying the pain than any known medication. Lorenz is astonished at the fabulous efficacy of the drug. In acute and chronic joint-rheumatism, acute muscular rheumatism, mastitis, panaritis, and contusions, a few rubbings, with pure or fifty per cent. ichthyol compounds, are peculiarly successful in allaying pain and hastening healing. In chronic and acute joint-rheumatism relief often follows a single rubbing, while this is the rule in acute muscular rheumatism. The pain of gout disappears, the shining red skin becoming quickly wrinkled. A beginning mastitis or panaritis is always aborted, or if fully developed, the pain is much relieved. Its prompt use prevents the discoloration following contusions. It immediately allays the pain of a burn and prevents blistering. Finally, a ten per cent. solution hastens the cicatrization of badly-healing ulcers. Loring dilutes the drug with water when pure ichthyol compounds cannot be borne, and prevents irritation of the skin by careful washing and drying before each application.

Von Nussbaum states that a single application of ichthyol one part, water four parts, lanolin five parts, has allayed the itching of eczematous ulcers which had resisted all known applications for weeks and months, and promptly brought about rapid cicatrization on being continued a few days. Arthritic pains, which for weeks have made day and night miserable, are relieved at times in one-half minute after the application of a strong ichthyol ointment. In erysipelas it produces results obtainable by no other means, namely: the immediate arrest of the disease. Von Nussbaum's treatment was first the thorough disinfection and drainage of the wound, then, if the disease continued to extend, over its whole surface a thick layer of ichthyolate and vaseline, equal parts, was spread, and covered by a layer of ten per cent. salicylated cotton. The erysipelas advanced not a line further, and in a single

day the swelling disappeared, and the red, shining, puffy surface became yellow, brown, and wrinkled. This remarkable effect Von Nussbaum ascribes not to the influence of the drug on Fehleisen's cocci, but rather to a change produced in the tissues, by virtue of which they cease to favor the growth of the micro-organisms. Stelwagon has had excellent results in the abortion of furuncles by ichthyol preparations.

Agnew (D. Hayes) considers the ichthyol preparations more powerful than any known therapeutical agent in bringing about reduction of inflammatory enlargements, and has had particularly good results in recently enlarged lymphatics. He uses sulphichthyolate of ammonia and iodide of lead, equal parts, applied generously and covered in by oiled silk.

The writer has used ichthyol in: (1) Six cases of cervical adenitis, with absolutely no relief; cure being subsequently brought about by iodine or the knife. (2) Fifteen cases of marked inflammatory induration of the subcutaneous tissues, with invariably a speedy and in some cases almost magical reduction, and this after other means had been tried unsuccessfully. (3) In two cases of furuncles without good effect. (4) In one case of cellulitis without marked effect till the knife was used. (In this case staphylococci were found, but no chains.) (5) In four cases where pain was the most marked feature of inflammation, with complete relief in three and no effect in the fourth. (6) In one case of erysipelas of the scalp, with immediate cure. The latter is so striking that it is reported in full:

B. C., bartender, aged thirty-six, a full-blooded Irishman, was struck on the head by a bottle whilst intoxicated, December 20, 1887. Two slight wounds of the scalp were inflicted, to which no dressing was applied. On Dec. 22, the symptoms were chill, fever, nausea, great pain in the head, and swelling. He then went to a clinic; wounds were opened, disinfected, and catgut drainage provided; symptoms progressive. He was seen by the writer on the second day of his fever, the fourth from the infliction of the wound. He had had no sleep for two nights; the pulse was 106; temperature 103°; violent headache; whole scalp puffy, œdematous, and very tender; a few drops of thin pus were squeezed from the wounds. Cover-glass preparations of blood from puncture by tenotome showed Fehleisen's chains. A saline purge and iron were ordered internally. On the scalp was placed a thick layer of ammonium ichthyolate and vaseline, equal parts. The pain was relieved almost immediately; the patient slept comfortably; his temperature the following morning was 98°, and he was and remained well.

This is not different from the results obtained by Nussbaum. With the exception of the case of erysipelas, the writer used a ten per cent. ointment of ammonium ichthyolate in lanolin, fearing lest, in the case of stronger applications, his effects might be ascribed to counter-irritation. It is possible that stronger preparations would have proven efficacious in the treatment of cases of adenitis, in which the weak ointment signally failed. The extravagant praises bestowed by some authors on ichthyol savor more of proprietary advertisements than scientific contributions, and the variety of affections for which it is recommended might well make one doubtful as to its complete efficacy in any single instance.

An analysis of the cases in which it has proven serviceable will show, however, that they can be relegated to one of two classes: 1. Affections characterized by inflammatory enlargement. 2. Affections characterized by pain of peripheral origin, probably depending on inflammation or congestion.

For either of these conditions, theoretically, a powerful antiphlogistic would be indicated, so that the clinical indications for the use of the drug correspond to its alleged therapeutic effect. When the surface is irritated, weak solutions (three to five per cent.) should be used; but when the skin is intact and the subcutaneous tissues are to be affected, pure or one-half strength ointments give the best results. In using strong preparations the skin should be washed with soap and warm water, and thoroughly dried before each application. Ichthyolates can be combined with any of the ointments, or can be dissolved in water.

The writer's success with the drug, even where it was not used in the most efficient manner, has convinced him that the praise bestowed on it by the Germans is well merited. Where suppuration has actually taken place the weak ointment is not of service, but in the allaying of inflammatory pain and the resolution of subcutaneous induration (excepting adenitis) the results are most satisfactory.

Dr. A. J. Downes read a paper on

Some Interesting Sequelæ of a Case of Scarlet Fever, with Pathological Specimens.

On November 15, 1887, at 3 P. M., I was asked to see B. M., a boy of seven years, then under the care of a homœopathic practitioner, and said to be dying of heart disease. I called

immediately. The boy was comatose; had been so for twelve hours. The face had a characteristic pallor, the eyelids were slightly puffy, the pupils dilated, the breathing stertorous. I listened to the heart, and heard a loud systolic apex murmur, a diastolic one at the base, and mingling with both a peculiar whistling sound, the cause of which at the time I did not understand. Examining further, I found that the eyelids had become puffy two days previous, that the feet and ankles were now swollen, and the scrotum slightly so. No urine had been passed within twenty-four hours. Excepting a few scybala, forty-eight hours before, the bowels had not moved in seventy-two hours. The child had had scarlet fever five years before. I told the father that the boy did have heart disease, but that he was dying of uræmia. Shortly after 5 P. M. the boy was dead. The following morning Dr. Martin Rively and I made a post-mortem examination. The specimens I show are the heart, kidneys and a piece of the liver. So advanced cardiac lesions in a child of this age are far from common. The ventricles are both hypertrophied and the cavities dilated; the right considerably. The curtains of the mitral valve are thickened and fibrous, the posterior leaflet is exceedingly contracted, and shows above it a recent inflammatory area. The aortic curtains are a beautiful picture of an insufficient valve. The whistling sound I heard during life must have come from the tricuspid valve. The hypertrophy of the muscular elements of the ventricle, with the marked distention to which the cavity was subjected, surely allowed sufficient leakage to cause this sound.

On account of its so late recognition and its undoubted influence in enhancing the cardiac condition, the state of the kidneys is exceedingly interesting. Even macroscopically the kidneys show changes which must have been going on for some time. The pale cortex and the eversion of the cut edges indicate fat. Under the microscope we find evidence of long existing changes, sufficient to warrant the assumption that the kidney changes began in the long-ago attack of scarlet fever. The tubules are swollen, distorted and full of casts. The epithelial cells lining them are somewhat granular and smaller than normal, with their nuclei becoming indistinct. Long existing changes therefore exist. We find also recent conditions. The glomerules are swollen and congested, and in their vicinity an infiltration of small indifferent cells—a very characteristic glomerulo-nephritis of recent date—which was the cause in this case of anuria and consequent uræmia. And the history points to this; for the boy, although not well for a few years back, was comparatively so. For two weeks previous to his death he was confined to his bed, and undoubtedly during this time he was suffering from a glomerulo-nephritis, which, adding itself to an already damaged kidney, precipitated an attack of uræmia. Additional proof that the boy's kidneys were not normal prior to his last sickness is not wanting. His bladder, on post-mortem examination, was found to contain about two ounces of urine—the accumulation of twenty-four hours—of this I collected one ounce. It contained a large amount of albumin, but no sugar; round and columnar epithelial cells, showing fatty degeneration; a few epithelial casts containing oil globules and some free oil. A few weeks' nephritis could not cause this condition of the urine. The liver changes are secondary to the heart condition. Under the microscope it shows both fatty infiltration and degeneration.

In concluding, I would recall the points that interested me in the case. 1. The extensive cardiac lesions caused by scarlet fever occurring in a child under two years. 2. The late recognition of the heart affection; the non-recognition of the kidney condition. 3. The occurrence of acute inflammation—the glomerulo-nephritis almost typical of scarlet fever—in an already damaged kidney. Finally, may I not call attention to this case as showing to what extent the sequelæ of scarlet fever may advance when not recognized and treated. And the history of the past proves such to be the fact. Eight homœopaths in succession had charge of the boy for four years prior to his death. Over a year ago one had diagnosticated diabetes. The one in attendance before my visits had recognized valvular affection. But the kidney lesions had escaped them all. Apparently this proves that the case ran an almost natural course.

Dr. James Tyson exhibited

Fleischl's Polarizing Saccharimeter,

made by Reichert, of Vienna, and explained its use. The deviation is indicated by the displacement of a dark band continuous in two parallel spectra, when no glucose is interposed and the instrument reads 0. When a column of sugar is interposed a deflection takes place, and after the continuity is again restored the *percentage* of sugar is read off from the vernier.

Dr. Tyson said the polarizing saccharimeter could not be recommended for testing qualitatively very minute quantities of sugar, say anything less than one-half of one per cent.,

Fehling's solution being really more delicate. Nor can it be said that there is any saving of time in testing qualitatively solutions contain less than one per cent. The advantage of its use is shown in determining from day to day the quantity of glucose in specimens containing considerable amounts, where the requisite dilution and titration occupy much time. In very clear urines it is not necessary, with Fleischl's instrument, to decolorize with acetate of lead solutions, but where they are not almost colorless it is necessary to treat with basic acetate of lead in the proportion of 1 c. c. to 10 of urine and filter, when one-tenth should be added to the reading of the vernier.

In opening the discussion, Dr. L. Wolff said: The instrument to which Dr. Tyson referred, and which I had the honor to bring before you here, is known as a polarization microscope, though this is an improper term, as it is simply the utilization of the microscope stand for the adjustment of the parts of a polarizing saccharimeter. I imported the parts constituting this about a year ago from the manufacturer, Paul Waechter, of Berlin. Its principal advantage is that of price, which, to the best of my recollection, is about twenty-five dollars when bought here. Like all other saccharimeters it consists of a polarizer which, as you see, is attached to the substage; on the top of this fits a plate consisting of two demi-disks of quartz of opposite rotary power, which let the intersecting line be readily seen through the analyzer. This latter, with the vernier and nomus, fits into the microscope instead of the draw-tube. The analyzer or scale can be so adjusted that when the nomus points to 0° the two semi-disks will be of an even neutral violet tint. In this position it is fixed with a screw. The tube is then withdrawn and the glass container with the urine is screwed in, when the whole is replaced. In looking through the instrument it will now be seen that the two semi-disks are no longer of neutral tint, but one is red and the other blue. On the rotation this inequality of color will disappear at a certain point, and when the neutral violet tints are again seen, the angle is read off. With this angle you can refer to the accompanying table and read off the amount of sugar present in grains contained in one litre, or by dividing this by ten the percentage will be arrived at. I have used this little instrument a great many times and find that it is quite as accurate as the larger and more expensive apparatus.

It is my custom to make about six readings, which is very rapidly accomplished, and take the mean thereof by dividing the sum of the readings by six. With some practice and an eye trained for color, the results come generally within one-tenth of one per cent. of the amount of sugar present. Like every other instrument, it requires practice to get good and accurate results. While for those who have to make many quantitative determinations of sugar in urine, the polarizing saccharimeter offers great advantages, I quite agree with Dr. Tyson that, for single and isolated determinations, Fehling's method is quite as rapid and certainly as reliable. The general use of the polarizing saccharimeter, together with its advantages and disadvantages, and also the preparation of the urine for that purpose, have been so fully explained by Dr. Tyson that there is nothing further for me to add.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 2, 1888.

The President, A. Jacobi, M.D., in the chair.

Dr. Robert W. Taylor read a paper on

Xeroderma Pigmentosum, and its Relation to Malignant New Growths of the Skin.

The author continued the histories of seven cases of xeroderma pigmentosum which he had reported in two papers, the first published in 1877, the second in 1878, showing their further development and relation to malignant new growths of the skin, and also gave a synopsis of cases reported by other observers in different countries, the entire number being thirty-nine. One other was excluded as having an incomplete history. The first paper on the subject of xeroderma pigmentosum was published in a text-book by Hebra and Kaposi in 1870. A good proportion of the entire number of cases observed had been reported by American physicians. The name xeroderma pigmentosum was not altogether satisfactory, but it probably would remain because of its brevity. The parents of all of Dr. Taylor's cases were dark brunettes; those of six were Hebrews; they were healthy; all the children were dark complexioned and had dark hair, except one. Three were sisters, and their parents were cousins. Two others were cousins of these, and their parents were second cousins. One patient had died of drowning before the development of malignant disease. Three of the others had epithelioma on some part of the face. The clinical history in the seven

cases was very similar, and was clearly portrayed. The disease consisted in telangiectasis, pigmentous and atrophic changes, which had close anatomical relations. To these polymorphous lesions were superadded new growths, which at first were benign in character, but which might become malignant. In six of his cases, according to reliable testimony, the disease began about the fifth or sixth month of life, and in one at the fourteenth month. He was skeptical about three cases reported as xeroderma pigmentosum beginning at the sixteenth, ninth, and ninth years respectively. The development of epitheliomatous and other malignant growths on the face of persons subject to deep or light pigmentations did not necessarily constitute xeroderma pigmentosum. The weight of evidence, therefore, placed this disease as one of very early childhood.

The invasion of xeroderma pigmentosum was very constant, beginning about the face and under the eyes as a well-marked smooth superficial erythema, which was often regarded by parents as the result of sunburn. The patches gradually spread over the face and neck and stopped abruptly at about the third rib. Its duration varied from one to seven months, during which the erythema might become less red, while pigmentous patches developed, at first of light-brown, then becoming darker, perhaps black. They varied in size from that of a pinhead to that of a lentil. Scattered among them were telangiectasic spots. With the evolution of these lesions there were no marked local subjective symptoms. If the case were carefully studied and frequently observed in these irregular patches, it would be very often plain to the eye that the pigmentary spots followed exactly upon the pre-existing red spots, and the conclusion would be obvious that the red lesion was its forerunner and its pigmented fellow its sequel. These lesions had exacerbations and remissions. As the child grew older the disfigurement became worse. There was no record of a case in which anything like an amelioration in its course had been observed. In the milder cases there was liability later in life to severe lesions.

The telangiectasis and the pigmentation were lesions of what might be called the hypertrophic stage of xeroderma. In some cases there were soon superadded atrophic changes. In the majority of cases these began at about the end of the first year. Their course was subject to marked exacerbations and remissions. They were not symmetrical on the two sides. As they progressed, they produced hideous deformities by reason of the size and situation of the patches. The skin became reduced to the thinness of parchment; nearly all the follicles were destroyed; vessels could often be seen beneath. The hands and arms, feet and legs, showed the changes less well marked. Atrophic changes were especially liable to be marked upon the forehead, scalp, eyes, nose and mouth, and might create partial stenosis of the nose and mouth. It was an interesting fact that when the atrophic process was at an end, no further pigmentation took place. Excessive hypertrophic changes took place very often coincident with the atrophic changes. There were also found epithelial new growths in rudimentary form, which might go on to malignant new growths. These tumors were liable to fall off and leave a fungous, oozing surface, which might become malignant. Such tumors and oozing surfaces should be removed or scraped by the sharp spoon. Of the thirty-nine cases, malignant new growths were known to have developed in sixteen, and non-malignant growths in six. Of course, the latter might yet become malignant, and some not yet affected by malignant or non-malignant growths might become so. Most of the new growths developed before the tenth year; there was nearly equal tendency to them between the tenth and twentieth years. There had been no evidence of metastasis during life or at autopsy.

The author thought the facts in the cases bore out Kaposi's explanation of the occurrence of epithelioma at so early an age, viz.: that it was due to the rapid changes going on in the epithelial layers. No successful remedy had been found. Surgery should be resorted to for the removal of tumors and fungoid surfaces. The sooner they were destroyed, the less the likelihood of their change into malignant new growths.

The President suggested the use of arsenic and phosphorus in treatment, for the purpose of causing nutritive irritation in the connective tissue, which seemed to be lacking, probably because of failure of embryonic cells to undergo their usual change after birth.

—The Otological Congress will be held at Brussels from the 10th to the 15th of September next, and it will be followed by the meeting of the German doctors and naturalists at Cologne. Dr. C. Goris, 143 Rue Royale, Brussels, will receive all announcements for the Otological Congress, which may be sent to him.

Reports of Clinics.

COLLEGE OF PHYSICIANS AND SURGEONS.

MEDICAL CLINIC—PROF. DELAFIELD.

Two Cases of Incipient Phthisis.

Case I.—At the Vanderbilt Clinic, January 12, 1888, the first patient introduced by Prof. Delafield was a young man who gave the history of a single hæmoptysis. After the physical examination, Dr. Delafield said: The patient is a very good example indeed of a class of cases we see more frequently in private practice than in dispensaries and hospitals. We find, often enough, patients coming to us with just the history which this man gives: a young man or a young woman who has been in ordinary health, with no cough, no running down, suddenly coughs up a little blood. The quantity of blood which such persons will cough up varies; it is, as a rule, not great; it may be only a few mouthfuls; it may be a cupful. In some, there may be a history of only a spitting up of blood; in others, it may have been repeated two or three times, but each time only a small quantity is raised. Between the attacks they may have a little cough, but not much. These will be all the rational symptoms the patients will give. This young man continued to have a good appetite; he slept well at night; he did not feel sick. But, on the other hand, if the patient is of a more excitable temperament, you may rely upon some constitutional disturbance. Many such patients will tell you they have no appetite; they feel very weak; they do not sleep at night; they feel very badly. Now, all this means the individual; it does not mean the disease. In most of them you will find no rise of temperature; in a few, there will be a little rise. The pulse is usually rapid, somewhere about 100°, as in this young man.

After getting the history of these patients, the next thing is to examine the chest. In some of them you will get absolutely no physical signs of disease; in most of them there will be no change in the breathing or percussion note over the entire chest. In other patients, there will be physical signs, but they will be very slight indeed. In these patients there is no consolidation of the lungs. When you listen to the breathing you will, in some patients, get a little information. The locality at which you will get this information varies in different cases. In some, it will be just at the apex on either side beneath the clavicle; in others, it is lower down in front, but not in the intermediate position. In other cases it may be over the upper part of the chest behind. What you first notice is change in the character of the breathing; this change is perhaps impossible to describe in words, but there is a difference in the breathing over the two lungs. There may be added to the change in the character of the breathing a few subcrepitant râles—not many, but a few. Now, with these very few physical signs, or no physical signs at all, you will be called upon to say whether the patient has or has not commencing phthisis, and you see how very difficult indeed the problem is to solve. It is easier to solve in men than in women, for men are less likely to bleed in this way than are women without showing changes in the lungs.

Suppose the case of a young man, like the one before us; it will make a difference, in the first place, as to what the patient tells you of the character of the bleeding. If he has had a single large hemorrhage, taking place within a short time, it will not be as much an indication of commencing phthisis as if he had had several smaller hemorrhages. The more frequently the hemorrhages have been repeated, so much the more likely are you to find disease of the lungs. Then you have to look at the throats of such patients, and see whether there is marked evidence of pharyngitis. This young man has none at all. Then you inquire particularly whether there has been any change in the general health. Sometimes on close questioning you will find that although the patient has considered himself well, yet he has not been in as good health as for sometime before; he has been running down, losing flesh and strength. Still further, you will inquire into the family history, to find out whether there is any hereditary predisposition to lung trouble. Thus you try to get all the collateral information you can about the health of these patients before you make up your mind as to what is the matter. Still further, in interpreting the physical signs, if there be any, you must have some definite idea of what they may mean. For example, in this young man the only physical signs are, that behind, over the upper part of the right lung, there is a little change in the breathing, and there are a few subcrepitant râles. Now, in interpreting those physical signs, there are two points to be borne in mind, namely, the mechanical conditions which produce

them, and the significance which they possess. In interpreting these physical signs we must take into consideration the patient's history. If this patient had come here without any history of spitting up of blood, but simply complaining of a little pain over the right shoulder, I would suppose that the subcrepitant râle present here was due to fibrine on the pleura, and that very probably the man had only a localized pleurisy. But when I get the history of a young man spitting up blood for several days in this way, and in his usual health, I think those subcrepitant circumscribed râles mean something else; I think they mean either a little mucus or a little blood in some of the small bronchi of that part of the lung. The sound is just the same, but the way in which it is produced is different. But with the history given, I do not draw the inference from these physical signs that the patient has simply a localized bronchitis. The inference which I draw therefrom is that there are a few scattering miliary tubercles in the upper part of the right lung; these miliary tubercles, as such, not taking any part at all in the production of the physical signs.

It is hard to realize in these cases of early phthisis that what is really of consequence is not the part which at first gives the patient either the symptoms or the physical signs. It is not the fact that there are tubercles in the upper part of this man's lungs that is occasioning the hemorrhage. It is not their presence which is occasioning the subcrepitant râles; yet we know by putting such cases together over and over again that with such a history and such physical signs we may be reasonably sure that there are miliary tubercles in the patient's lungs. Still more than this, we may be pretty sure that if he had not miliary tubercles he would not have had the bleeding, and he would not have the physical signs.

I think, then, in this patient's case there is no question about the diagnosis. He has phthisis in its very earliest stages, consisting of a very few miliary tubercles in the upper part of the right lung. As a symptom of this change in the lungs he has had spitting of blood, which, by the by, comes from the bronchi of that lung, and from the larger bronchi, not from the lung tissue. With this bleeding from the bronchi there has been a very small degree of bronchitis, or perhaps no bronchitis at all. Perhaps the subcrepitant râles are due simply to a little blood which has been expelled from the larger bronchi into the smaller ones.

As to the treatment, I think one has to admit that such patients as these really can get well without doing anything at all. I think it is possible for a young man like this to stay in the same place, go on with his work, and have no further symptoms at all, and if he should die years afterward from some other cause, you would find in the upper part of his lung the miliary tubercles which are there at the present time, the disease not having progressed. This is, I think, possible for these patients; the probability, however, of their getting entirely well is very much decreased if the patient cannot take proper precautions in preserving his health. The best precaution of all is probably one which this young man cannot take, and that is getting the beneficial effect of change of climate. If you could do just what you think is the very best thing to do for a young man coming to you with such a history, and with such physical signs as these, you would tell him to go away for one or for two years, and during that time to travel about from place to place, not staying in any one locality, not looking out particularly for climates which are considered good for patients with phthisis, but simply getting the beneficial effect on his whole body of traveling and moving about from place to place. If he cannot do this, the best thing he can do is to try to remedy any defect which there may be in his general health. Take the case of this young man. He is sufficiently well nourished; that is, he has fair weight; there is no object in giving him cod-liver oil; there is no object that I know of in giving him stimulants. There are only two points about his case which suggest themselves to me as giving indications for treatment. One of these is his occupation. He is a cigar-maker. That unquestionably is an unhealthy occupation for a young person with lung trouble of this kind, as the dust from the tobacco is constantly being inhaled. He is still young, and if it is possible for him to take up some other business it would be very much to his advantage.

Then in color he is slightly anæmic; and this indicates the administration of iron. In this case, then, all that is necessary is to advise him to learn some other way of earning his living than working in tobacco, and have him for a time take iron in moderate doses.

Case II.—This case makes a sort of continuation of the one which we have just been considering. The man is 30 years old, and instead of raising blood only six days before coming under observation, he has been having hemorrhages during the last eighteen

months, but much in the same way as the other patient. Although the duration in this second case has been longer, yet you will observe there is the same paucity of symptoms as in the other. He has no cough except at the times he raises blood. He is not short of breath; he has no great amount of pain about the chest; his appetite is fairly good, but latterly he has lost flesh to some extent; that is all. Now in his case we ought to find more physical signs, and rather different physical signs from those we found in the previous case. There is a little depression under the clavicles, but it is about the same on both sides. You will notice the difference in the percussion note on the two sides. On the right, beneath the clavicle, the resonance is fair enough; but on the left the pitch is higher, and the sound is a little shorter. The breathing is not quite as loud on the left side of the chest beneath the clavicle as it is on the right, and the voice is decidedly more feeble.

This man began eighteen months ago, just as the preceding patient has begun recently, with a few miliary tubercles in the lung; but, instead of having them in the upper part of the right lung, he has had them in the upper part of the left lung. Whether he had any physical signs eighteen months ago or not, of course we do not know; but he had the same spitting of blood. He has gone on from that time to the present, spitting blood occasionally; yet, for the most part, not feeling sick; able to work; but latterly he has lost flesh. He says he could work, but he has nothing to do. When we come to examine his chest, we get the physical signs which we would expect to find with his clinical history. We no longer get any râles, although in other patients of this kind we might very well get some subcrepitant râles. All we get is dullness on percussion, not very marked, the breathing not as loud, and the voice not as loud under the left clavicle as under the right. These are the physical signs.

Now, what is the change which has taken place in his lung? It is a very limited one, indeed. It involves only the apex of the left lung. Here at the apex is the same moderate number of miliary tubercles as in the previous case. But, as this man's trouble dates back eighteen months, there has been time for changes to be added to those of miliary tubercles, and it is these other changes which give rise to the physical signs. In the first place, the pulmonary pleura is thickened over or just below the apex of the lung. In all probability, there are some adhesions between the pulmonary and costal pleura at this point. Then in the lung itself, besides the miliary tubercles, which still are few in number, there is a little diffuse fibrous tissue. It is not the tubercles which give us the dulness; it is the thickening of the pleura; it is the pleuritic adhesions and the fibrous tissue in the upper part of the chest which give us the difference in the percussion note, voice and breathing. It is easy enough to say why these changes produce the difference in the percussion note, but it is not by any means easy to say why they give the difference in voice and breathing. We know by experience that they do so; we see it, over and over again, that those are all the changes in the lungs to account for the voice and breathing being diminished.

In this man, then, we have chronic phthisis lasting eighteen months, yet at the end of that time he has but very slight pathological changes in the lung. In such a case as this the prognosis is comparatively good. It is perfectly possible for such a patient to get well. As to what we can do for him, the rule is just the same as in the preceding case. If it were possible for him to go away and stay away, it would be the best thing he could do. His occupation, when he has it, is that of a salesman, which is a good enough business for a man suffering from his trouble. Just now, unfortunately, he is out of work, and leading the very demoralizing life which belongs to a man without work. He has nothing to do all day, and he loafs about the house, and has not sufficient exercise either of body or of mind. He unquestionably would be better off if he had something to do. In the next place, in this man there is an indication for fattening food. He has lost flesh. He is somewhat emaciated. His lips are not particularly anæmic. I do not know that there would be any particular object in giving him iron. I would rather give him cod-liver oil.

—Dr. George S. Meigs, a dentist living in New York, killed himself Jan. 23, 1888, in his operating-room. He had become subject to extreme nervousness, which interfered with his work and kept patients from him. When utterly prostrated, he consented to try the so-called "Christian Science," in the hope that it might restore him to health. It failed, and in despair the wretched man put an end to his life. He made death sure by drinking enough prussic acid to kill twelve men. He stated, in a letter to his wife, that he wished to be cremated.

Periscope.

Contributon to the Etiology of Neuralgia.

In the *Edinburgh Med. Journal*, December, 1887, Mr. James R. Whitehall says there are many conditions classed under the heading neuralgia. There is the pure form, with no apparent and definite cause during life, and leaving no discoverable lesion after death; the reflex form, which may be, and frequently is, due to dental caries and other remote causes, the removal of which gives speedy relief to the symptoms. Then, again, there are other forms due to an actual inflammation of the nerve—a true neuritis and not a neuralgia at all; others due to poisons circulating in the blood, such as lead, the poison of syphilis, gout and malaria; and some to pressure upon the trunk of the affected nerve, or to an irritation still higher in the course of the nerve. In the pure form of neuralgia, where there is no apparent cause except the debility so frequently associated with it, the author thinks it is impossible to distinguish during the attack these three different kinds of pain: First, a more or less continuous throbbing pain; second, a sharp, lightning-like pain, succeeded frequently by a burning or tingling sensation; third, a superficial cutaneous hyperæsthesia, the "points douloureux" of Valleix. The throbbing pain he attributes to a dilatation of the vessels of the nerves themselves; the sharp, lightning-like pain to a more acute compression of the nerve, brought about by a sudden alteration in the blood pressure, or an increased dilatation of the already dilated blood-vessels, perhaps from such slight causes that they usually escape notice. With regard to the production of the tender spots of Valleix, the explanation is ingenious. As the nerve, he says, passes on its course, it gives off filaments to the surrounding parts, and these filaments come off from the main trunk in a definite order from without inwards; therefore the most superficial filaments of a nerve-trunk are those which supply the tissues in the immediate vicinity. But it is these very filaments which suffer most when a nerve is compressed in the osseous or other canal; and therefore, by the law of eccentric projection, there is a hyperæsthesia in the part supplied by those filaments—in fact, a tender spot. And since these filaments suffer most, it is not at all unlikely that, as the attack progresses, the prolonged pressure would temporarily destroy their function and cause local anæsthesia; and this is exactly what occurs—hyperæsthesia being more likely to occur at the earlier part of an attack, and anæsthesia later.

He considers the treatment of neuralgia under three headings, namely: 1, external local; 2, external remote; 3, internal.

1. Of the local methods of treatment, such operative methods as incision and division of the nerve sufficiently explain themselves. Stretching the nerve and acupuncture seem to act in the same way, probably by causing a solution of continuity in the sheath, and thus relieving tension, and diminishing the swelling of the nerve. As regards stretching, however, Callender considers that "it is probable that the stretching is of use by numbing the nerve for a short time." If this be really true, the natural explanation would be that the sensory irritation resulting from the hyperæmia would for a time cease, and on its cessation the reflex dilatation of the blood-vessels would also be brought to an end. Electricity, again, in common with belladonna and heat or cold locally applied would contract blood-vessels. Belladonna, volatile oils and their stearoptenes,[1] such as thymol and menthol, also chloroform, not only contract the blood-vessels, but also diminish the sensibility of the part, while aconite locally applied acts purely as an anodyne.

2. Of the external and remote methods of treatment, counter-irritation over the upper part of the dorsal spine, which apparently does good in some cases, must be mentioned, though perhaps somewhat difficult to explain, unless possibly it has some action on the sympathetic vaso-motor fibres which emerge from the cord about this level in the anterior roots of the lower cervical and upper dorsal nerves (Foster). Ligature of the carotid is an eminently successful, though somewhat heroic treatment, and has been very successfully employed by Dr. Patruban in many cases of severe neuralgia—this, of course, acting directly on the blood-vessels, the idea of the operation having originated from the relief obtained in some cases by simple pressure on the carotid.

3. Of the internal treatment of neuralgia the substances used fall naturally into four groups:

(1.) Those which contract blood-vessels, such as strychnia, atropia, and its allies, bromide of camphor, digitalis, ergot, volatile oils, such as turpentine, chloride of ammonium and quinine, though certain of these also have a specific action on sensory nerves in addition.

[1] Solid crystalline compounds separable from volatile oils by cold.

(2.) A second group consists of bodies which act as general tonics, such as quinine, iron, strychnia, phosphorus and arsenic. The experience, however, of arsenic and phosphorus seems to indicate that they have some more direct action than simple tonics.

(3.) A third group consists of simple anodynes or sedatives, such as bromide of potassium. This, however, like chloral, diminishes the pulse tension, and in addition diminishes reflex excitability by depression of the peripheral sensory filaments. Other drugs, such as cannabis indica and morphia, seem to act as simple anodynes.

(4.) The fourth group consists of the usual tell-tale drugs, which are always appearing, and of the action of which no very apparent explanation can be given. Amongst these gelsemium sempervirens is a prominent member, and probably also arsenic and phosphorus.

He concludes by saying that there are, then, symptomatic, pathological, etiological, and therapeutic reasons for believing that the blood-vessels are at fault in cases of neuralgia, and therefore, on this view, it seems necessary to consider true neuralgia as a sympathetic neurosis, affecting certain tracts of cerebro-spinal nerves, resulting in simple dilatation of the vessels of these nerves, brought about by unknown causes, or by reflex irritation, or possibly by the specific action of certain poisons in the blood.

Sulphate of Sparteine.

The *Deutsche med. Wochenschrift*, in a review of sparteine, remarks that it is the alkaloid of broom, and belongs to the alkaloids which have no oxygen in their composition. The sulphate is employed for medical purposes, because it is more easily soluble and less easily decomposed than the other salts. It forms large, translucent, colorless rhomboid crystals, readily soluble in water, and of a bitter taste. Germain Sée found that it possessed a stimulating action upon the contractions of the heart, slowing its action; and that it increased the arterial tension, and also increased the flow of urine. The rhythm of the heart's contractions was restored in only a few cases. The action of sparteine was rapid, but was not maintained sufficiently long at its height to remove the disturbances in compensation; and even when given in repeated doses does not achieve any such persistent action as is obtained through the use of digitalis. Voight, however, recommends it in valvular disease, with and without the disturbances in compensation which are proper to it. He also recommends it as a regulating and calmative agent, in insufficiency of the heart muscle without disease of the valves, in pericarditis, and finally as an adjuvant in combination with digitalis. The dose is about one-third of a grain, three times a day. The following formulæ are given:

℞ Sparteini sulph.....gr. iij
Aquæ destillat.....f℥ij¾
M. Sig.—20 drops in sweetened water or wine, two to four times daily.

℞ Sparteini sulph.....gr. iij
Syr. aurantii cort .....f℥iij
M. Sig.—Dose, a small spoonful in water, four times a day.

Saccharin in Diabetes Mellitus.

Kohlschütter and Elsasser report to the *Deutsches Arch. f. klin. Med.*, xli, S. 178, that in a case of severe diabetes affecting a man 30 years of old, which was treated with saccharin in daily doses of 15 to 30 grains, a considerable though transient diminution in the quantity of urine and sugar was brought about. During the employment of these large doses, anorexia persisted. The patient complained of a persistent disagreeable sweet taste, even when the saccharin was given in pill form, which taste hindered the taking of nourishment through the disgust it produced. The authors refer the diminution in the quantity urine and sugar excreted to the smaller quantity of food taken. But inasmuch as the saccharin effected no increase in the production of sugar, it may be used without injurious results to sweeten food and drink in diabetic patients. In one case in which the drug was given in this way the sweet taste of the saccharin was noticeable throughout in a disagreeable way.—*Centralblatt f.d. med. Wissensch.*, Jan. 7, 1888.

Case of Carcinoma of the Cervix in a Virgin.

Eckhardt reports this case to the *Arch. f. Gynecologie*, xxx, S. 471. It is interesting from the fact that a cancerous tumor, the size of a child's head, which arose from the hypertrophied posterior lip of the uterus, was found in a girl who was unquestionably a virgin. This tumor was removed by means of the galvano-cautery écraseur. The cause of the snout-shaped hypertrophy, as well as of the carcinoma, is stated to be chronic irritation from masturbation. At first the tumor was thought to be a carcino-sarcoma; but on microscopic examination epithelioid cells with large nuclei were found, not spindle cells.

Foreign Body in Wharton's Duct.

At the meeting of the Boston Society for Medical Improvement, November 28, 1887, Dr. A. T. Cabot showed a piece of brown straw, one inch and one line in length, and as large as a No. 5 needle, which had lodged for six months in Wharton's duct. The patient, a young man, lost a piece of straw under his tongue on the 14th of May, 1887. For three or four weeks he experienced no trouble from it. Then a somewhat painful swelling of the submaxillary gland upon that side occurred. When seen in August, the submaxillary gland contained a hard swelling about the size of a robin's egg, and in the line of the duct, about one inch from its orifice, was a little hard swelling as large as an apple seed. Pressure along the duct caused the issue of a drop or two of pus. The bit of straw being supposed to be very small and evidently lodged far back towards the gland, a cutting operation in search of it seemed unadvisable, and the patient was advised to press occasionally over the gland, and then along the duct, so as to force the pus and secretion out, in the hope of working the straw out along with it. This milking the gland and duct was followed by a decided increase of pain and swelling, but it was continued at intervals until October 1. At this time a little abscess formed over the duct, and was punctured by the patient. A few drops of pus appeared. On November 15, the patient found that when he gaped and raised his tongue, the duct was so shortened that the tip of the straw appeared at the orifice. After some trouble he succeeded in seizing the end with a fine pair of scissors and withdrew the straw.

Poulet, in his exhaustive work on "Foreign Bodies in Surgery," has succeeded in finding but six authenticated cases of foreign bodies in Wharton's duct. In one of these the foreign body was, as in this case, a bit of straw introduced while picking the teeth. A very severe inflammation followed in the case reported by Poulet, and, abscesses forming, the straw, which was two-thirds of an inch in length, was finally discharged spontaneously in two pieces. A careful search in this case at the time of opening the abscesses failed to find the straw. In answer to a question by Dr. Hooper, Dr. Cabot said that if he had suspected the size of the straw, he would have made an incision of the duct, and would have hoped to find it. The evidence at the time he saw the patient, however, was that the bit of straw was extremely small, and far back towards the gland, where the chances of finding it were but slight. As the patient was suffering no pain, it seemed better, therefore, to wait and try to work the straw forward to where it could be easily reached. That it was worked forward by the manipulation practiced seemed probable by the result.—*Boston Medical and Surg. Journal*, Dec. 22, 1887.

Chloroform and the Constant Current in Neuralgia.

Prof. Adamkiewicz says he has obtained marvellous results from the combined action of chloroform and the constant current in facial and other forms of neuralgia. The electrode is made of hollow charcoal into which the chloroform is introduced, and from which the current sends it into the tissues. That this power of penetration may be thus obtained is thought to be shown in the fact that when chloroform is colored with gentian violet and applied in the manner described to the ear of a rabbit, the tissue becomes dyed. In the experiments with the human subject, the writer notes, at the commencement, the triple action of the constant current, the chloroform and a condition of cataphoresis followed by a burning sensation and, finally, anæsthesia. Several remarkable cases of cure are cited. Anæsthesia was not obtained when the nerves were deep-seated, nor in sciatica.—*Progrès Médical.*

Tinea Decalvans.

At a recent meeting of the Academy of Medicine of Paris, a discussion took place on the contagiousness or non-contagiousness of tinea decalvans, but without much satisfactory result on either side. Dr. Ollivier has for the third time brought the subject to the notice of the Academy. The author protested vehemently against the exclusion in schools of the pupils who are affected by it, on the ground that it was not a contagious disease. Dr. Ollivier believes that tinea decalvans is caused by a sudden nervous perturbation, an unexpected emotion, or by very great sorrow. He would therefore recommend that the quarantine to which such pupils are subject should be removed, and that they should be allowed to prosecute their studies in common with the others. Dr. Hardy, the well-known dermatologist, declared that he entertained an opinion diametrically opposed to that of Dr. Ollivier. Prof. Cornil shares Dr. Ollivier's opinion, and stated that what tends to prove the non-transmissibility of tinea decalvans is that one does not find in this affection either cryptogams or micro-organisms, which could produce it.—*Lancet*, December 17, 1887.

Impaction of a Foreign Body in the Pelvis.

Upendra Nath Sen relates, in the *Indian Medical Gazette*, September, 1887, a remarkable case of impaction of a foreign body near the rectum. A washerwoman, aged 25 years, subject to epileptic fits, had an attack whilst in a standing position and fell over a bamboo. By the force of the fall a piece of a bamboo branch broke, and penetrated very deeply half an inch to the right of the anus. The wound proved to be very small, only admitting a probe, which entered to the depth of five inches; the presence of a foreign body could not be detected in it. As this, however, might have found its way into the rectum by the force of the fall, an exploration was made with the finger, whereupon a hard substance was felt in a vertical position by the side of the rectum, about two inches beneath the surface of the skin. The writer cut freely to the depth of two inches over the suspected part, and succeeded in feeling the end of the foreign body with a probe. He then enlarged the wound to the required extent, to facilitate the extraction of it, and with a strong forceps removed an entire piece of a bamboo branch four inches long and as thick as a full-grown finger. It is worthy of notice that the patient walked from her home, a distance of two miles, a fortnight after the accident. The woman is now doing well.—*Practitioner*, Dec., 1887.

Venesection.

At the meeting of the Clinical Society of Manchester, November 15, 1887, Dr. Addy (*Brit. Med. Journal*, Dec. 17, 1887) related three cases in which bleeding was performed, in two of which it rescued the patients from imminent death. The first case was that of a man, about 50 years old, who had suffered from hematemesis, cirrhosis, ascites and albuminuria. After recovery from these ailments, the patient, who had also aortic disease and high tension pulse, was seized with convulsions, lasting more than an hour; he became unconscious, cyanotic and breathed with great difficulty. About twenty ounces of blood were removed from the arm; the convulsions ceased, consciousness returned in twenty-four hours, and the patient had continued in good health for twelve months. The second case was that of an elderly woman, who was suddenly seized with violent coughing and dyspnœa, the lungs becoming rapidly engorged. On admission, the patient was almost pulseless, and apparently moribund. Venesection was performed, with almost immediate relief to the breathing, and the patient rapidly recovered. This patient suffered also from chronic Bright's disease. The third case was that of a young man, suffering from acute pneumonia; congestion of lungs rapidly supervened, and the patient seemed fast sinking. Bloodletting was tried, and relieved the embarrassed lungs and heart; but the improvement was only temporary.

Treatment of Rheumatism and Rheumatoid Arthritis.

At a meeting of the West London Medico-Chirurgical Society, held Dec. 3, 1887, Dr. Saville read a paper on the treatment of rheumatism and rheumatoid arthritis. The author took a peculiar interest in the disease, for he himself had been a martyr to it in its subacute form. He classified rheumatism into (1) acute, in which the temperature exceeded 102°; (2) the subacute, in which the temperature never reached 102°; and (3) the chronic form. He considered that the amount of fever and constitutional disturbance usually varied inversely as the age of the patient. He thought that the treatment of acute rheumatism by the salicylates of soda and potash, the best yet devised; and contrasted the old cases as described by Dr. Fuller twenty-five years ago—the majority of which lasted four or five weeks and upwards—with the experiences of the present day. The salicylate, properly used, now made the temperature go down in a few days, and in nearly every case the patient was quite cured within the month. He had seen no evidence that visceral complications were more frequent under the treatment. The failure of the drug may be due to three things: (1) Unsuitability of the cases, *e.g.*, where renal disease is present; (2) the mode of administration—large doses being requisite; and (3) errors of diagnosis—gout and septicæmia having been mistaken for rheumatism. He recommended graduated baths. In one case everything failed to relieve the pains but hypodermic injections of morphia. Dry and hot cotton-wool often gives relief. In the subacute and chronic forms he has tried many remedies, but cannot believe much in any of them. Saline purgatives and diuretics may be useful. Sometimes Scott's dressing and other applications, care in diet, avoidance of alcohol and sugar, warm clothing, a course of Turkish baths and massage—especially for muscular rheumatism, will be beneficial. Change of climate, mineral baths, and particularly pure sea air, as on a voyage, are useful by inducing metabolic change.—*Medical Press and Circular*, Dec. 14, 1887.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

EXCISION OF THE RECTUM—KRASKE'S METHOD.

At the Fourteenth Congress of the German Society of Surgeons, in 1885, Prof. Kraske, of Freiburg, proposed an ingenious method of operating for cancer of the rectum, which consists in approaching the diseased tissue, not from below but from behind, after removal of the coccyx, division of the left sacro-sciatic ligament and, if necessary, removal of part of the sacrum. Since this time, other surgeons have tested Kraske's method, and have found that it not only makes the removal of a portion of the rectum a more exact, and, in some respects, an easier operation; but also makes it possible to remove a portion much higher up than could be reached by any operation according to the older methods.

In his first description of his method, Kraske recommended, in cases in which removal of the coccyx and division of the sacro-sciatic ligament did not furnish room enough for access to a morbid growth situated high up in the rectum, that the sacrum should be chiselled away below a curved line passing from its border, at a point on a level with the third sacral foramen, to the border of the lower horn of the sacrum. Bardenheuer has proposed, as a better plan, a transverse exsection of all of the lower part of the sacrum. This plan is not only approved by Kraske, when it is absolutely necessary, but it was actually suggested by him in his first publication on this subject and has been done by him in one case. The consequences were not unfavorable in this case; but Kraske naturally and sensibly contends that such an exsection should not be regarded as preferable to removal of part of one side of the sacrum, except when the latter is insufficient for gaining access to the portion of the bowel to be removed.

In a paper in the *Berliner Klinische Wochenschrift*, Nov. 28, 1887, Kraske describes the method which, after considering the various proposals which have followed the first description of his method, he believes to be the best. This consists in placing the patient on his right side; making an incision from the middle of the sacrum to the tip of the coccyx, going down to the bone; detaching the soft parts on the left to the border of the sacrum and coccyx; division of the left sacral and coccygeal ligaments up to the level of the third sacral foramen; division of the soft parts over the coccyx to the right, and exsection of the coccyx with bone forceps. If now, when the soft parts are held apart with retractors, the portion of the rectum to be removed is accessible, its removal can be proceeded with. If it is not accessible, then the part of the sacrum indicated above may be chiselled away. If this does not furnish room enough, the sacrum may be reached at the level of the third foramen.

In regard to the actual removal of the diseased portion of the rectum, Kraske describes two methods: one proceeding from the anus, when the disease extends so low down that the lowest portion of the bowel cannot be saved; and the other following the general line of the preliminary removal of the bone, when the lowest portion of the rectum is not implicated. The limits of our space compel us to refer our readers to Kraske's

paper for the details of this part of the operation, which involve considerations which cannot be stated briefly.

Kraske urgently recommends saving the anus, with its sphincter, whenever it is possible, and suturing the upper portion of the bowel, after its resection, to the lower portion; and he has found it possible in his practice to do this successfully. In the paper to which we have referred Kraske gives an account of eight cases in which he has practiced his method, four of the patients dying soon after the operation, and four making a good recovery. In two of the latter cases the function of the anus was so good, after the wound healed, that the stools were passed in the normal way.

The opinions of Kraske appear so sound in theory, and they are so well supported by the results which he has secured, that they deserve the most careful consideration of surgeons, and we hope that they may receive such consideration, and a fair test in practice, not only in his own country, but also in ours.

OPERATION FOR ABSCESS OF THE SPLEEN.

In the *Deutsche Med. Wochenschrift*, December 22, 1887, Dr. Carl Lauenstein, of Hamburg, describes a case in which there was enlargement of the spleen, chills and fever, with pain in the region of the spleen, following an illness which had been diagnosticated as typhoid fever. After studying the symptoms carefully he came to the conclusion that there was an abscess in the spleen, and decided to operate for it. In carrying his decision into effect he first plunged an aspirator needle through the chest wall in the line of the axilla, passing through the eighth intercostal space, the pleura and the diaphragm, and into the spleen. Upon finding pus, he then—leaving the needle in place—resected a portion of the ninth rib as long as a finger. After this he proceeded to cut down upon the spleen with the thermocautery, and opened a pus cavity as large as a goose-egg. After fixing the spleen to the edges of the incision with tenacula, he washed the cavity out with a cold solution of salicylic acid, and tamponed it with iodoform gauze, and surrounded the chest with an antiseptic dressing. The subsequent history of the case was very satisfactory, the patient making a good recovery in about six weeks.

With this experience to guide him, Lauenstein has studied the literature of operations for abscess of the spleen, and has found none which is exactly like his own. Reflecting upon his operation and its results, he is disposed to attribute his success, in a large measure, to the preliminary partial emptying of the pus-cavity with the aspirator and the consequent diminution of tension in it, and to his leaving the needle in place while he completed the subsequent part of the operation. Another thing which contributed to the fortunate result in this case was the fact that the diaphragm was adherent to the wall of the chest, and was incapable of movements which might have contributed to infection of the peritoneal cavity. A practical conclusion from the features of this case is the opinion of Lauenstein that fixation of the diaphragm and basal pleuritis are not only important diagnostic signs in abscess of the spleen, but that they contribute materially to success in any operation for its relief.

This experience of Lauenstein, and the conclusions to which he has come in analyzing its details, are of more than ordinary interest for surgeons, and for physicians as well, to whom, in the first place, patients with diseases of the spleen present themselves. The operation which proved so successful in this case is not likely to be soon repeated; for such cases are fortunately very rare. But it is good to know what has been accomplished in one of them, in order that no patient may be permitted to succumb to an abscess of the spleen without duly weighing the possibilities of an operation for its relief.

LEGAL REGULATION OF THE PRACTICE OF PHARMACY.

There is, according to the *Concours Médical*, December 10, 1886, a proposed law before the Chamber of Deputies, of France, in regard to the practice of pharmacy, which has

some points of interest for physicians and pharmacists everywhere. The law makes a proper restriction of the exercise of pharmacy to those who have received a diploma of fitness. It also forbids any association between a druggist and a physician for their special profit, or for the pushing of a special preparation. It also forbids the practice of medicine and of pharmacy by the same individual, even if he has taken a diploma in both sciences. Physicians may furnish medicine in cases of emergency and urgency when the distance to the nearest pharmacy is not less than five kilometers (about three miles). A pharmacist may sell any simple or compound remedy upon demand; but he may not sell a remedy composed according to a physician's prescription, provided the prescription is so formulated that it may be understood by any pharmacist. Hospitals, and various societies and associations indicated, may have pharmacies of their own, provided they are in charge of qualified pharmacists.

Some of these provisions for the legitimate exercise of the functions of pharmacy are excellent; but we cannot see why a man who has the legal qualifications for the work of a physician and for that of a pharmacist should be forbidden to prescribe and dispense medicines. There are reasons why it is not generally advisable for a man to undertake to perform the labors of two callings, each one of which may demand so much time and skill as to preclude the possibility of attending properly to the other; but, in this country, a restriction of this sort would work hardship in many places in which the population is not large enough to support a druggist in addition to a physician.

As to the provision that a physician may dispense his medicines only in emengencies, and when the distance to the nearest pharmacy is not less than three miles, it may be said that such a proposition would not be listened to in the United States, and it is not likely to be adopted in France.

With these exceptions, we believe the provisions of the proposed French law to be wise, and worthy of imitation here. Druggists as well as doctors would, we think, be glad to have laws adopted in every State which would protect honest and competent pharmacists in the exercise of their calling, and define clearly their relations to physicians and to the community, while restraining the incompetent or unworthy from disturbing the harmonious and reciprocal working of physicians and pharmacists in their labors for the health of their fellow-men.

CIGAR-MAKING AND INSANITY.

The New York *Tribune*, January 20, 1888, states that, when Mayor Hewitt recently visited the insane asylum on Ward's Island, he was struck with the remark of Dr. Macdonald, Medical Superintendent, that cigarmakers were more largely represented among the patients than members of any other trade. On asking for the statistics of this institution, Dr. Macdonald informed him that, in the fourteen years during which he has been medical superintendent, 5733 patients have passed through the asylum. Of these there were: bakers, 79; barbers, 56; bricklayers, 31; butchers, 74; carpenters, 141; cigarmakers, 163; cooks, 52; masons, 66; painters, 126; plasterers, 17; plumbers, 37; printers, 94; shoemakers, 143; tailors, 178. Dr. Macdonald ascribes the large number of insane cigarmakers to the unhealthfulness of the surroundings under which the trade is carried on in this city, a large proportion of the cigarmakers working, cooking and sleeping in the same atmosphere in their tenement-house rooms.

On the other hand, President Bayles, of the Board of Health, finds that from 1874 to and including 1883, when the law was passed forbidding cigarmaking in tenements, the number of cases of insanity was 112, a yearly average of 11.2; and from 1884 to 1887, 51, a yearly average of 12.75. The number of insane tailors from 1874 to 1883 was 122, a yearly average of 12.2; and from 1884 to 1887, 56, a yearly average of 14. Mr. Bayles points out that the average number of cases yearly among the cigarmakers increased after tenement work was abandoned. He, therefore, does not attach much

significance to Dr. Macdonald's table. From all the information he can obtain, he sees nothing objectionable in the business of cigar-making in the tenements. He thinks tailoring in tenements much more objectionable.

In this Mr. Bayles appears to be in the right, and the statement of Dr. Macdonald seems to be an illustration of hasty generalizing from too scanty premises. When the figures for cigar-makers (163) are compared with those for tailors (178), it would appear that working on tobacco is not so dangerous as working on dry goods; and when both are compared with those for carpenters (141) and painters (126), it would appear that working in tenements is not materially more dangerous than working in the open air or where the air is as pure as falls to the lot of any mechanics.

As a matter of fact, any assumption founded upon these statistics, in regard to foul air or tobacco as influencing insanity, would not be unfavorable to either of them; and the statistics cited by the *Tribune* illustrate the trap into which one may fall who strains an argument in what may be a very good cause. Working on tobacco may be dangerous to the health; but the attempt to show that insanity can be attributed to it becomes ridiculous in the light of the statistics of the asylum at Ward's Island, if they are correctly reported by the *Tribune*.

In Austria the method of executing criminals differs from that in vogue in America; and, though apparently more horrible in its details, is more speedily effective. The condemned man is placed against a post, at the top of which is a hook and at the bottom a pulley. A rope having a loop at each end is passed around the neck of the victim; another is tied about his feet, the end being passed through the pulley. Two assistants then lift the man, by means of the rope around his neck, about six inches, and suspend him from the hook at the top of the post. At the same time the other assistants pull with great force at the rope attached to the feet. Death ensues usually instantaneously, though there is a range from one-half to two minutes in many cases.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

CHEMICAL ANALYSIS OF HEALTHY AND DISEASED URINE, QUALITATIVE AND QUANTITATIVE. By T. C. Van Nüys, Professor of Chemistry, Indiana University. With 39 wood engravings. Large 8vo, pp. 187. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $2.00.

In this manual, simple qualitative tests for analysis of the urine are given in full, and the rationale of chemical processes is fully explained, while to meet the requirements of students somewhat familiar with laboratory work, nearly all the methods employed in quantitative estimations are given in full; especially is this true in regard to processes peculiar to work in physiological chemistry. Five chapters are devoted to the Physical and Chemical Properties of Constituents of the Urine; one to the Examination of the Urine and Sediments; and one to the consideration of Concretions and Stones. The rest of the book is devoted to quantitative analysis.

The whole presents an admirable treatise on the subject of the examination of the urine, especially adapted to use in chemical laboratories, and suitable for men who wish to conduct such examinations in a strictly scientific way. It treats the subject in an exhaustive manner, and leaves nothing to be desired in the way of completeness.

If we were to criticise this work, it would be only from the standpoint of the average medical man, who would miss in it those practical applications of the information acquired in the laboratory, which are so great a help to the practitioner, as compared with the laboratory student. Most of the readers of the Reporter, we feel sure, would like to have the weights and measures which are given in the figures of the metric system, given also in English equivalents, or at least to have a comparative table of these measures embodied in the book. Such details are not needed by those who are daily engaged in the study of chemical problems; but most medical men cannot well get along without them.

With this exception, we find nothing to complain of in this book, which is clearly written, handsomely printed, and admirably illustrated.

SIMILIA SIMILIBUS CURANTUR? By Charles S. Mack, M.D. 8vo, pp. 31. Boston and Providence: Otis Clapp & Son, 1888. Price, 40 cents.

This little book is written by one who throughout it manifests a spirit so temperate and fair, that what he says merits very careful consideration. He is not a headstrong advocate of homœopathy; but he inclines to the belief that the application of medicines to the cure of disease may be guided by what is known as the law of similars. It is with some regret that we observe—after an admirable exordium—that the argument of this book is made in a vicious circle, and that its conclusion—moderate as this is—is not warranted by what precedes it. We have not space in which to expose what appears to us to be the fallacies of Dr. Mack's reasoning; but we must confess some disappointment that one who seems in many respects so well qualified to defend what he believes should not make out a better case for a belief which has always appeared to us to be illogical, but which we have no disposition to dismiss with a sneer.

After all has been said, we think no "law" of therapeutics can be stated which will bear close scrutiny; and that nothing better has ever been proposed for our guidance in the choice of remedies than the good old rule of experience—empiricism, in fact. So far, the pursuit of a "law" of therapeutics has been but a groping in the dark for most seekers after such a light, and a persistent following of an *ignis fatuus* for those who think they have found it.

Pamphlet Notices.

Foot and Mouth Disease as it Affects Man and Animals, and its Relation to Human Scarlatina as a Prophylactic, etc. By J. W. Stickler, M.S., M.D., Orange, N. J. From the *Medical Record*, Dec. 10, 1887. 31 pp.

Syphilis of the Endometrium. By T. A. Ashby, M.D., Baltimore, Md. From the *Maryland Medical Journal*. 16 pp.

Footprints of a Profession. By Horatio C. Meriam, D.M.D., Salem, Mass From the *Archives of Dentistry*, Nov. and Dec., 1887. 21 pp.

Miscellaneous Reprints. By James Craig, M.D., Jersey City, N. J. 31 pp.

The Eye of the Adult Imbecile. By Charles A. Oliver, M.D., Philadelphia. From the *Medical and Surgical Reporter*, Sept. 17, 1837. 4 pp.

Traumatic Hæmatoma of the Larynx. By J. W. Gleitsmann, M.D., New York. From the *Medical Record*, Oct. 29, 1887.

Hypertrophy of the Tonsil of the Tongue. By J. W. Gleitsmann, M.D., New York. From the *Medical Record*, Dec. 17, 1877. 11 pp.

A Study of the Causes and Treatment of Uterine Displacements. By Thomas Addis Emmet, M.D, New York. From Volume xii, *Gynecological Transactions*, 1887. 14 pp.

—Dr. Stickler's paper deals with a subject of the greatest interest and importance. It contains an admirable description of foot and mouth disease in human beings and in the lower animals of the equine and bovine species, and a very interesting study of its relation to scarlet fever. The chief interest and value of the paper lie in his study of the relation of this disease to scarlatina. The conclusion to which he comes, and which he states with praiseworthy reserve, is that foot and mouth disease and scarlet fever are so related that the inoculation of human beings with the virus of mild aphthous fever in cattle may serve as a prophylactic against scarlet fever. This conclusion and Dr. Stickler's reasons for it may well be recommended to the consideration of our readers, who will find food for much thought in his interesting paper, to which we have already referred in an editorial in the Reporter for Feb. 4, 1888.

—In this pamphlet, Dr. Ashby gives the history of two cases in which miscarriage attributed to syphilis was followed by prolonged and stubborn sub-involution of the womb, and metrorrhagia. These he thinks were also attributable to syphilis. He does not assert this dogmatically; but says he has never seen any cases so difficult to manage, and can find no explanation of the fact more reasonable than the one he proposes. Other observers may have had similar experiences, to which this explanation would not apply; but Dr. Ashby's paper deserves consideration and may throw an important light upon an obscure subject.

—Dr. Meriam is a dentist who was graduated at the Harvard University Dental School, and who thinks dentists should be more than mere artisans; and he endeavors in this pamphlet, which contains an address he delivered before the Maine Dental Society, at its 22d annual meeting, in July, 1887, to impress his fellow-practitioners with the importance of observing a system of ethics like that established for the medical profession. He is especially opposed to the practice of patenting instruments or appliances, and of permitting what should be the common property of all who are engaged in the healing art to come under the exclusive control of manufacturing firms. These views, which must commend themselves to the judgment and sentiment of those who regard dentistry as a profession, he supports with argument and pleasantry, which make his address as entertaining as it is instructive.

—Dr. Craig's pamphlet contains a variety of short communications on medical subjects, several of which have appeared in the Reporter. One of the most interesting of these concerns a case of precocious menstruation. The subject was a child who began to menstruate when only four years of age, and continued to menstruate regularly until she was ten years old, when she ceased menstruating until she was fourteen years old, and then began again.

Another communication brings forward a claim for priority in the use of an elastic rubber band for ligating the umbilical cord, which the author recommended before the Medical Society of New Jersey in 1870.

—Dr. Oliver's short paper gives the results of the examination of the eyes of twenty young adult imbeciles. His conclusion is that the eyes of such persons show the effect of intellectual hebetude in the absence of changes frequently found in those who use the eyes constantly.

—Dr. Gleitsmann's paper contains an account of the case of a man who had a hæmatoma of the larynx as a consequence of a blow upon it with the fist of an assailant. In addition to the interest attaching to this case in connection with the general subject of laryngology, it is curious to note that the blow caused temporary insensibility, confirming the recent experimental demonstration of Brown-Séquard that such a result may follow such a cause.

—Some of our readers may be surprised at the term "tonsil of the tongue," as the word "tonsil" is usually applied to what anatomists call the "faucial tonsil;" and they will be interested to learn that aggregations of glandular tissue exist at the base of the tongue, which are but part of a ring of glandular tissue surrounding the opening of the mouth into the pharynx. These masses may become hypertrophied, just as what are usually known as the tonsils do, and when this happens they are to be treated by reduction or destruction of the redundant tissue. For the details of this treatment we must refer our readers to Dr. Gleitsmann's interesting and instructive paper.

—Dr. Emmet's paper ought to be read by every man who wishes to treat displacements of the uterus rationally. His large experience gives great weight

to what he says, and those who have treated cases of the kind he discusses must share, to a certain extent at least, his strong objection to the indiscriminate use of pessaries. He sees plainly that it will be hard to wean men from a practice which has the sanction of so much authority and experience, but he brings forward reasons for its restriction which appeal strongly to the judgment, and which ought to be weighed most carefully by those least inclined to accept them.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The *Caledonia Springs Sanitarian*, published at Caledonia Springs, Ontario, once a month, four pages, quarto, price ten cents a year, is the lowest priced semi-medical periodical we have seen yet. Its appreciation of the Reporter is seen in the fact that it looks to this journal for assistance in editing it. We observe, for example, in Vol. II, No. 2, January, 1888, one of our recent editorials on "Some Points in the Care of Children;" but we are pained to observe that the printer has cut out the reference to the source from which it was taken, which we feel sure the editor of the *Caledonia Springs Sanitarian* must have been careful to put in.

—The *Cyclopedia of American Contemporary Biography*, "from Abbe to Anderson," is received from John B. Alden, New York. It includes notices of men and women of the United States, prominent in the life of to-day. It is to be issued in small 8vo volumes of about 550 pages each, brevier type, including numerous portraits, and is to be revised and re-issued as often as annually. Volumes bound in fine cloth, price $1.00, postage 12 cents. The specimen we have received is interesting, and promises well for the whole work. We remark the absence of the names of a number of distinguished medical men in this city, which ought to have been included in a work making any pretension to completeness; but, as far as it goes, the list is useful.

—The attention of persons interested in historical or scientific investigations, or in the making of books of substantial character, is invited to the proposals of *The Editorial Research Company*, of Philadelphia, which is composed of persons who have had many years' editorial experience, and who are convinced of the need of such an agency as they have established. This company offers its assistance to persons engaged in literary work, in making researches, gathering statistics, making transcripts or translations, correcting manuscripts, and preparing indexes or reviews. Persons desiring further information as to the purposes of the company may address *J. P. Lamberton, Secretary*, 721 South Sixteenth street, Philadelphia.

—The J. B. Lippincott Company announces the intended publication of a *Cyclopædia of Diseases of Children*, to be edited by John M. Keating, M.D, of Philadelphia. The list of contributors, who have agreed to share in the preparation of this work, includes the names of a large number of well known writers in this country and in England, and justifies the expectation that it will be a work of very great value.

Correspondence.

Sudden Death After Typhoid Fever.

Editor Med. and Surg. Reporter:

Sir:—On January 11, 1888, I was called to see a young man, 17 years old, who was suffering with an attack of typhoid fever. I attended him regularly for twenty-four days, when he died suddenly and unexpectedly, having presented no unfavorable symptoms until within a few hours before his death. At the beginning of his illness his temperature rose gradually until, on the eighth day of the disease, it was 103°. After this it fell gradually until, on the twenty-fourth day, it was 102½°. At this time his tongue and the surface of his body were moist, and his pulse was about 90–95, and full and strong. He had some headache during the first few days, as is usual in typhoid fever, but was perfectly rational up to the time of his death. He had no diarrhœa at any time; neither was he constipated to any marked degree. Castor oil was administered two or three times with gently purgative effect. His bowels moved three days before his death. He had no trouble, which was discoverable, with his urinary organs, his urine being voided freely and in quite sufficient quantity. He never had any extensive tympanites, or excessive tenderness over the bowels, but was troubled somewhat more than is common with pain, though this was generally controlled with warm fomentations. Opiates were resorted to only a few times. He had no trouble with his lungs, except a very slight bronchitis, which was not as marked as is usual in this disease. His tongue was heavily coated for the first ten days, when it began to clean off. The only thing in its appearance, which I did not like, was the fact that the papillæ seemed to be rather prominent, and that the color was a slight shade redder than is usual in mild cases. The surface never became very dry. He took milk every day in sufficient quantities. In fact, he progressed favorably up to the twenty-fourth day, at noon, when I visited him.

I had given a favorable prognosis all along, and could not see anything in his case which should cause me to do otherwise. But at about 11 or 12 o'clock at night, he began to be restless and short of breath, while his pulse became quick, and remained so all night. The next morning (the twenty-fifth day), at 8 o'clock, I was called to see him, and to my great astonishment I found him with a pulse of 150, the first sound of the heart inaudible, with great distress in his breathing, a very

anxious expression, and an appearance of being in pain. When asked if he were suffering pain, he said: "No, not of any consequence." I at once recognized his great danger; but was at a loss to account for it. My first impression was that perforation of the bowels had taken place. But finding no vomiting, no more tympanites, no more pain, no more fever, and the patient able to move himself without pain, and other symptoms of perforation being absent, I concluded that it must be a case of sudden heart failure, and so expressed myself. As I have already said, he was never irrational, even to the last.

My experience with typhoid fever dates back nine years, and I have treated cases every year; but this case was different from any I have ever seen. I would be pleased to have an expression from you, or from any of your readers, as to the immediate cause of death. Yours truly,

S. M. Hunter, M.D.

Hope, Kansas.
February 1, 1888.

[The facts stated in this letter do not warrant any positive expression of opinion; but the explanation offered by Dr. Hunter, as to the *immediate* cause of death, seems to be entirely rational.—Editor of Reporter.]

Sulphate of Magnesia for Warts.

Editor Med. and Surg. Reporter:

Sir:—*Apropos* of recent statements as to the efficacy of sulphate of magnesia in the treatment of warts, I would like to mention the following case which recently came under my notice: A man consulted me respecting a growth of vegetations surrounding the glans penis, forming a huge mass, almost as large as a hen's egg. I prescribed the use of a powder of equal parts of salicylic acid, calomel and oleate of zinc, to be renewed night and morning. The case improved slowly, too slowly for the patient's satisfaction. I then ordered one grain of sulphate of magnesia every hour, in solution, in addition to the application of the powder already mentioned. The growths now commenced to disappear rapidly, and in less than three weeks there was not a vestige of them left. The patient states that they mysteriously "melted away." He used the magnesia regularly, every hour of the day for the first week, but became more careless for the rest of the time. Yours truly,

Louis Lewis, M.D.

800 Corinthian Avenue, Philadelphia.
Feb. 4, 1888.

Correction.

Editor Med. and Surg. Reporter:

Sir:—In my article on *Diphtheria, January 28, 1888*, page 100, the direction for gargle should read: "*Gargle well every two hours*, or *ten minutes each time before taking the medicine.*" The direction in the second spray should read: "*Spray each time before giving the medicine, and apply a cloth dipped in cold vinegar*, not too wet, to the neck." Further down read: "*Elix. phosphate iron quinia and strychnia with liquor potassæ arsenitis.*" In the last formula read: "*I order syr. ferri iodidi and liquor potassæ arsenitis to be taken after meals.*"

I think a great deal of all arsenical preparations in cases of debility, as well as in all chronic affections.

Yours truly, J. Pirnat.

Evansville, Ind.
Feb. 2, 1888.

Koumiss and Lupulin.

Editor Med. and Surg. Reporter:

Sir:—In the present volume of the Reporter, page 125, you copied from the *National Druggist* directions for making koumiss. I would suggest the addition of one teaspoonful of *lupulin*. I have been accustomed to make the addition in several of those fermentative mixtures where there is considerable nervousness of the patient. It will be found soothing and exhilarating.

John M. Currier, M.D.

Newport, Vt.
Feb. 6, 1888.

Masturbation in Women and Girls.

Editor Med. and Surg. Reporter:

Sir:—I was glad to see the article in your columns entitled "Masturbation among Women and Girls." This is a delicate subject to treat, but it surely comes within the province of a medical journal. I believe that the vice to which you allude is not so common as many people suppose. At the same time, its frequency in ancient and modern times among women of indolent, luxurious and voluptuous habits is unquestioned. Here, heredity, high living, and artificial and precocious stimulation of the sexual appetite are, as you have intimated, powerful factors in bringing about the practice of this vice. It is hard to believe that the "gentler," "purer" sex can become so depraved; but it is not to be expected that the daughters will be much more virtuous than their fathers, and shameless women are not a rare phenomena even

in this Christian land. You speak of the preponderant influence of the sexual passion in the thoughts, imaginations and lives of multitudes—a fact for proof of which your readers will not have to go far. As for the allusion to the popularity of certain filthy French novels, it is gratifying to be able to chronicle the fact that the worst kind of French romances have not been reproduced, and cannot be reproduced in this country or in England.

I have personally seen comparatively little evidence of masturbation, though occasional instances are constantly coming under my observation. I fancy that most physicians hesitate, like myself, to interrogate their female patients with regard to these practices, though they may often have reason to suspect that such practices exist. Glaring instances will, however, now and then present themselves where complete physical and moral ruin has resulted from the unnatural indulgence. One such instance I saw some years ago, in which the beginning of the vicious habit could be clearly traced to the manipulations of a servant girl. Another girl, 13 years old, the daughter of a clergyman, seemed to have contracted the habit from "pure cussedness," and was one of the most remarkable instances of "innate depravity" that I have ever seen. In her case the habit was most inveterate, beginning at the age of six years; and no amount of moral suasion or correction, and no punishment availed to stop the pernicious habit altogether. Even when this girl was put in a straight-jacket and watched day and night, she found some means of exciting the sexual orgasm, and bringing about the abominable gratification. For aught I know, this patient, who is now grown to womanhood, is in daily practice of the habit. The mind has been enfeebled and the body dwarfed—in fact, this unfortunate being is a perfect nonentity as far as concerns her relations to her family and to society.

Another young girl, 7 years old, a patient of Dr. Healey, was broken down physically and mentally by the vice, and is to-day an inmate of the insane asylum at Danvers, Mass. Dr. Healey, moreover, tells me that he has at the present time under his care a female infant, only 2 years of age, who is a confirmed masturbator.

Such instances might be multiplied from the experience of many of your readers. The inveterate female masturbator is generally a hopeless case. Much can doubtless be done by every intelligent physician in inculcating among his patrons a knowledge of the existence of the vice and its dangers, and insisting upon the proper hygenic means of prevention, so that no undue awakening may be given to an appetite which nature intended should slumber till maturity; which even then ought to be very sparingly indulged, and by many persons, I think, never at all. It is not alone the appetite for strong drink that requires regulating, if not suppressing.

E. P. Hurd, M.D.

Newburyport, Mass.,
Feb. 6, 1888.

Notes and Comments.

Dizziness from Injuries to the Tympanum.

Dr. A. D. Williams reports in the *St. Louis Med. and Surg. Journal*, January, 1888, that a young man recently received a severe blow upon the left ear from a wagon stake, and was knocked senseless for a while. The ear bled freely at the time, and after recovering from the headache and the immediate effects of the blow, the patient found that he had difficulty in hearing with the ear which had been injured, and complained of a sense of numbness, or a "muffled feeling" therein. The history of the case showed plainly that there had been a rupture of the membrana tympani, but when Dr. Williams examined the ear, two weeks after the injury, there was no sign of a rent, the injury having healed so perfectly that he could not even discover its previous location. The patient, however, was so dizzy at the time that he could not walk straight, and staggered about like a drunken man. The cavity had evidently filled with blood at the time of the injury. He catheterized the drum, and found it very difficult to get the air into the cavity. The operation gave great relief to the patient, but it lasted for only a few minutes. While there might have been other injuries inflicted by the blow in this case, the author thinks the dizziness resulted entirely from the obstructed condition of the drum. In a recent case a similar phenomenon was observed. A young woman slipped and fell, striking the side of her head flat against the pavement. She at once noticed that her hearing was muddled, and that the ear on which she fell "felt as though it had been stuffed full of something," to quote her own words. On attempting to stand, she found herself so dizzy that she was compelled to catch hold of something to support her. Twelve hours after the injury he made an examination, and found a bloody line just behind the handle of the malleus, and running its entire length, showing that the

rupture of the membrane was an extensive one. While the ear did not bleed any externally, the cavity was most likely filled with blood. As the injury was still fresh, and the rupture was nicely coapted but not yet healed, he thought it best not to interfere at the time, but told the patient to return later, which she has not yet done. The cases are given to illustrate the point which the author has made before, that great dizziness frequently results from the filling up of the drum cavities, and that, in fact, very grave brain symptoms are frequently traceable to this cause, especially in childhood.

Laparotomy for Incised Wound of the Stomach; Recovery.

Dr. J. A. Black, M.D., reports the following case in *Daniel's Texas Medical Journal*, December, 1887: William Edwards, 17 years old, was stabbed, while attending a country dance, on July 20, 1887, at 9 o'clock P.M. The long blade of a large pocket knife entered the abdomen at the left side, immediately below the lower margin of the ribs, about five inches from the median line, making an external wound two inches long, which extended toward the median line, and parallel with the margin of the ribs. From this wound undigested food and blood escaped.

On July 21, at 9 o'clock A.M., twelve hours from the time of the injury, Dr. Black saw the patient for the first time. He had tossed about all night in great pain, and without medical attention. He was given anodynes and placed in a position which favored the escape of the food and blood until assistance could arrive. Four hours later, Dr. Black and Dr. T. J. Bennett, of Austin, proceeded to operate by enlarging the original cut in the direction of the median line. First an incision about two inches in length was made, which, proving to be inadequate, a further incision was carried to the median line, making a total external opening of five and a half inches transversely across the abdomen, terminating just below the xyphoid cartilage. Several large fish bones, some of them over an inch in length, and a quarter of an inch in diameter, together with a quantity of undigested food, and some blood, were found lying on the great omentum and intestines, and were removed. The small intestines, as well as the transverse and a portion of the descending colon, were pulled outside, laid upon aseptic towels, and searched for wounds, but none were found. The investigation was extended above the line of incision, when it was found that the blade had passed through the great omentum and entered the stomach near the center of the great curvature, making a wound about one and a half inches in length. The stomach was then drawn outside, and two interrupted and two continuous sutures, making four in all, were made in the wound. Fine iron-dyed silk was used to close the wound. Catgut was thought of, but it was feared that the gastric juices would digest the sutures before union could take place. As the stomach was pulled outside vomiting took place, and some depression was noticeable for a short time. It is worthy of note, that, while vomiting was taking place, the stomach was held in the hand of the operator, and the firm and uniform contractions, which the muscular structure of the stomach would indicate should take place in vomiting, were actually felt. Absorbent cotton was used instead of sponges. The viscera were carefully cleansed and returned, and the abdominal cavity mopped out with the cotton. No irrigation was employed. The external wound was then closed by eight interrupted sutures of strong iron-dyed silk, the peritoneum being included in each one. Space was left for the escape of pus, in case any should form. Iodoform and carbolated absorbent cotton, confined by a broad bandage, tightly applied, constituted the dressing. The patient was placed on his back, with the shoulders elevated, and a roll of quilt placed under the knees. Anodyne and nutrient enemas were ordered, and only ice water was allowed to enter the stomach. The position of the patient, and attention to the bladder, etc., constituted the chief directions given the nurse after operation. Although the external wound suppurated and the patient was subsequently attacked with colliquative diarrhœa, so severe as to threaten life, he ultimately made a complete recovery.

An English View of Homœopathy.

The *British Medical Journal*, referring to some recent statements by Lord Grimthorpe, remarks that the latter has a boisterous rhetoric, and wields the literary truncheon with quite a special gusto. He is not infrequently, and always noisily, at fault; and rarely more so than in his present assault on medical men who decline professional association with homœopaths. In the main he strikes wide of the mark. No one pretends that "homœopathic" practice is illegal, any more than "magnetic" practice, or "faith-healing." But homœopathy, in the opinion of medical men generally, is either a nullity or a fraud. Under this conviction, which is shared by

the wisest and the best among us, medical men habitually decline to consult or to act professionally in concert with "homœopaths." This Lord Grimthorpe decribes as "boycotting." If so, it is only a new name for a very old practice, which the bar, equally with the profession of medicine, have found necessary to maintain a due standard of professional sense and morality. If a barrister were to see clients and receive instructions without the intervention of a solicitor (a purely artificial restriction), what course would his professional fellows and the class of solicitors adopt? The professional etiquette and the rules of the practice at the bar are in many ways more restrictive than those of the profession of medicine and more severely enforced. Everyone who pleases is free to practice "homœopathy," or any other "pathy" he can practice in this country with or without education, and with or without a degree. A penalty is incurred only on the false assumption of a title. It is open to Lord Grimthorpe or to anyone else to consult him or to build hospitals for him to practice in. But it is certainly not in his power or his right to constrain the great body of highly educated men who regard such practices as frauds, or nullities, or public dangers, to enter into or to countenance any professional alliance with their professors. His violence, his threats, and his rhetoric appear, therefore, to be alike thrown away.

Treatment of Carotid Hemorrhage.

Mr. Frederick Treves, surgeon to the London Hospital, in a communication upon the treatment of carotid hemorrhage to the *Lancet*, Jan. 21, 1888, remarks that he thinks the ligature of main arteries for the arrest of bleeding in distant parts is often somewhat blindly advised, and possibly too frequently carried out. He reports four cases in which, instead of tying the artery, he passed a ligature around the common carotid, and kept up traction upon the ligature for some time after the hemorrhage ceased. The method proved satisfactory in every case. One patient, a child three years old, died six days after the operation, but death was the result of exhaustion from previous hemorrhage. The hemorrhage was in all four cases of a grave character, and such as, in three of the instances, one who adhered to the usual surgical practice would have controlled by means of ligature of the common or external carotid. By the exercise of careful antiseptic precautions, he thinks that no very serious risks attend the operation itself.

The Medical Societies of Brooklyn.

There are no less than six different societies in Brooklyn organized and maintained for the advancement of medical science. Some of these bear in their titles the name of the county rather than that of the city; but their membership is made up mainly of residents of Brooklyn, which city is in fact the greater part of the County of Kings in respect to population. These societies are: the Medical Society of the County of Kings, the Brooklyn Pathological Society, the Medical Microscopical Society of the City of Brooklyn, the Brooklyn Surgical Society, the Kings County Pharmaceutical Society, and the Brooklyn Dental Society.—*Brooklyn Medical Journal*, January, 1888.

A Doctor Classed as a Commercial Traveller.

The Paris correspondent of the *New York Medical Journal*, February 4, 1888, says: Another case of professional interest was decided by the Paris tribunals lately. A doctor had agreed with a druggist to write articles recommending a certain chemical product manufactured by the druggist, and also to deliver lectures in regard to the product, recommending it, in fact, by all possible means to his professional brethren and the public. In consideration of these services the druggist agreed to pay the doctor 4000 francs a year and certain expenses. Afterward the doctor refused to continue the work for the druggist, who at once sued him. The doctor's lawyer maintained that he could not be compelled to carry out such a contract, as he was not a man of business. The tribunal, however, decided that, as the doctor had agreed to do work such as an ordinary commercial traveller did, he was responsible. It was added that a physician should only advise any preparation which he knew to be useful in the ordinary way of giving advice at his office or at a patient's house, and not by advertisements; and that he should not receive any payment for such advice, beyond his usual professional fees, under pain of being ranged with the regular mercantile traveller. This would not be a bad judgment on those who recommend certain preparations, for a consideration, in other countries!

Successful Excision of a Tumor of the Spinal Cord.

At a meeting of the Royal Medical and Chirurgical Society on Tuesday, January 24, 1888, Mr. Victor Horsley presented the patient from whom he had removed a myxoma

of the spinal cord on June 9, 1887 (see REPORTER, July 23, p. 126, 1887). It is interesting to learn that, following the operation, the pain from which the patient had suffered acutely was for a time slightly relieved, but again and again recurred with great severity, and the power of motion was only slowly and intermittently regained during the first three or four weeks. Pressure over the wound was obtained by a pad and strong jacket; the local pain gradually diminished; the motor power gradually returned to the lower parts; and, after seven months, the use of the lower limbs, though a little stiff, had become almost natural, and the remains of the laminæ had come so near together in the well healed cicatrix that any further external support seemed unnecessary.

Charges against an Eclectic Physician.

A despatch from Chicago to the New York *World*, January 20, says: A. B. Pullman, brother of George M. Pullman, of the Pullman Palace Car Company, has begun a suit for $25,000 damages, charging criminal malpractice against Dr. Pingree, an eye and ear specialist, for whom it is understood a warrant is out. Mr. Pullman's wife has had a cancer on the nose for about ten years, and it has eaten away the greater part of that organ, greatly disfiguring her face and endangering her life. Dr. Pingree has been treating it for the last two years, and Mr. Pullman alleges that he used violent remedies which made the cancer worse. Dr. Pingree was graduated at the Bennett College of Eclectic Medicine and Surgery, Chicago, in 1880.

Prescription for Chronic Cystitis.

Prof. Brinton recommends (*College and Clinical Record*, January, 1888), for chronic cystitis:

℞ Uvæ ursæ..... ℥ij
Lupulini..... gr. xv
Aquæ bullient..... f℥vj
Misce. Ft. infus. et adde
Sodii bicarb..... ʒss
Tinct. opii camph..... f℥j
Aquæ..... q. s. ad f℥viij.
M. Sig.—Tablespoonful four times a day.

Ointment in Small-pox.

The following ointment is said to act as an anæsthetic and antiseptic, and to prevent pitting:

℞ Pulv. iodoformi..... ʒss
Pulv. camphoræ..... ʒi
Vaselini puri..... ℥j
Misce. Ft. ung. Sig.—Apply by gentle inunction to the affected parts of the skin.

NEWS.

—Dr. Harvey Shoemaker and Dr. Thompson S. Westcott have been elected resident physicians of the Pennsylvania Hospital in its Insane Department.

—Recent reports from San Remo regarding the condition of the Crown Prince of Germany are rather unfavorable, and it has been found necessary to perform tracheotomy earlier than was at first expected, in order to relieve the difficulty in breathing.

—It is reported from Springfield, Illinois, that scarlet fever is prevailing in Pana, on the Ohio and Mississippi Railroad, to such an extent that the public schools have been closed. There have been two deaths, and fifteen cases of the disease were reported on February 4.

—The committee of the New York Academy of Medicine, appointed to coöperate with the Health Board of that city, has made its report to Mayor Hewitt. The committee consisted of Drs. C. R. Agnew, E. C. Janeway, Stephen Smith, A. Jacobi, T. Mitchell Prudden, H. M. Briggs, and Richard H. Derby. The Mayor requested the committee to make an early examination of the Quarantine establishment, point out its defects and requirements, in order that it may be brought up to the highest ideal standard of modern scientific and medical knowledge, to estimate the sum required to be appropriated by the state in order to complete the necessary improvements, and to suggest whether New York should provide any further temporary hospitals in case there should be an outbreak of cholera in the city.

The character of the report is such as to excite concern in New York in reference to the miserable condition of things at Quarantine. The *Tribune* says, Jan. 3, 1888, "So long as it continues the entire country is confronted with an appalling danger. When such an able committee as that which presents this report unites in confirming in detail all that the public has long feared with regard to Hoffman Island, it is high time for action. The medical committee has performed its work with commendable completeness. It shows what must be done and just how to do it. The Legislature will doubtless be its own best judge of how the suggested commission should be composed, but the evidence now before it of the necessity of providing the island with adequate facilities for holding imported contagion in check is too abundant and too serious to be disregarded."

HUMOR.

A GEORGIA FARMER made one hunderd dollars off an acre planted in watermelons, and a neighboring doctor made two hundred dollars off the same acre.

FAITH CURE AND PHYSIC.—Gus De Smith—"I've been reading about a remarkable faith cure." Gilhooly—"I don't believe in it. Physic beats the faith cure every time." Gus De Smith—"Well, it ought to; it has the inside track."

A FORMER PATIENT met a doctor who practiced at a mineral spring, in Germany, and said to him: "Why, doctor, if you are a physician to the springs, how comes it that I find you in Frankfort?" "Well," replied the doctor, "you see I am a physician to the springs in summer; in winter I collect patients."

LADY (handing prescription ordering pil. aloes et ferri gr. vj; mitte iv): "Make up this prescription, please. How much will they be?"

Chemist: "Sixpence."

Lady (astonished): "Oh! dear, no! they will be more than that; *that is one of Sir William Gull's prescriptions.—Chemist and Druggist.*

A YOUNG PHYSICIAN, who has just established himself, and has very little practice, is noted for his braggadocio. One of the older physicians, meeting him on the street yesterday, asked him how he was coming on. "I've got more than I can attend to," was the boastful reply; "I had to get out of my bed five times last night." "Why don't you buy some insect powder?" asked the old doctor.

NEW USE FOR ICE.—"I'm going to Maine after a consignment of ice for consumption in Washington," said an Avenue dealer to a new reporter nosing around for an item.

"Indeed," exclaimed the reporter, pulling his note-book, "that's something new. I didn't know before that ice was a remedy for consumption."

The city editor saved the reputation of the paper.—*Washington Critic.*

OBITUARY.

E. MILES WILLETT, M.D.

Dr. E. Miles Willett, Professor of Clinical Medicine in the Memphis Hospital Medical College, and Supreme Medical Examiner, Catholic Knights of America, died suddenly on February 6, 1888, at his residence, in Memphis, Tenn. He was graduated at Jefferson Medical College in 1855.

GEORGE W. TRYON, JR.

Mr. George W. Tryon, Jr., who died on February 5, 1888, at the age of 50 years, was the most eminent conchologist in this country, if not in the world, and a highly valued member of the Academy of Natural Sciences.

WILLIAM ASHMEAD, M.D.

Dr. William Ashmead died at his home in Germantown on February 2, 1888, aged 87 years. He had been a practicing physician in Philadelphia for upwards of fifty years; but, about ten years ago, he withdrew from active service and retired to his home in Germantown. He was connected with the State and County medical societies, and took considerable interest in other professional and scientific associations. One of his most recent acts of benevolence was the contribution of $3000 to the Wills Eye Hospital.

E. J. SNITCHER, M.D.

Dr. E. J. Snitcher, a well-known physician of Camden, N. J., died on February 6, 1888, in his 39th year. He commenced the study of medicine in the office of Dr. N. S. Davis, of Chicago, in 1872. In March, 1874, he was graduated from the Chicago Medical College, and subsequently removed to Camden. In 1876 he became a member of the Camden County and the New Jersey State Medical Societies. He was a director of the Camden City Dispensary until impaired health made it necessary for him to retire.

E. J. ENGLEMAN, M.D.

Dr. Edgar J. Engleman, a well-known physician, died on Monday, February 6, 1888, at his residence in Philadelphia, at the age of 74 years. He was graduated at the Jefferson Medical College over fifty years ago, and practiced his profession for a number of years in the West. Until recently, he lived at No. 701 Pine Street.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Clinical Lecture.

OSSIFLUENT ABSCESS; OSTEITIS OF THE PELVIS.

BY PROFESSOR TERRILLON,
SURGEON TO THE SALPETRIERE, PARIS, FRANCE.

(Translated by E. P. Hurd, M.D.)

Gentlemen:—I shall take as the subject of to-day's lecture two patients, one of whom is a youth 16 years of age, the other a woman 29 years old. The first patient has been suffering from slight pains and soreness in the anal region; then a well-defined swelling appeared there, which had attained the size of a large chestnut, when it was recognized as an abscess and opened by a physician who was called in. The incision did not heal, and there remained a fistula which proved utterly rebellious to treatment. This fistula remains to-day, and gives vent to considerable clear serous pus, mixed here and there with a few drops of blood. By the side of this fistulous orifice, you may see a little purplish swelling, which projects somewhat above the surface, is indurated, and presents a characteristic to which I invite your attention, namely, that it rests on a base which is hard and painful to pressure. By the fistula neither gas nor stercoraceous matters find vent, and though one would be inclined at first to regard it as a fistula in ano, he is soon convinced of his mistake. Indeed, if you explore the tract with a probe, you see at once that the instrument takes a direction away from the rectum, which shows that the disease is not a simple anal fistula; the probe, in fact, penetrates two inches at least in two different directions, but always externally, with an inclination towards the ischium. This exploration, moreover, enables you to determine the existence of profound detachments of tissue.

If at the same time that you make this examination you introduce the finger into the rectum, you can easily ascertain that it is separated from the probe by quite a considerable thickness of tissue, which seems hard, especially on the side toward the ischium, and this materially helps the diagnosis. Here, as you should always do when it is possible, you ought to compare the diseased with the well side. The pulp of the finger turned toward the internal aspect of the right ischium finds nothing abnormal; the suppleness of the tissues enables you to feel the hardness of the bone; the same exploration, on the contrary, when made on the left side, where the fistula is seated, reveals the presence of an induration which is precisely the same as that indicated before by the probe, and which gives a very different sensation from that given by the healthy bone on the other side. If you press upon this induration the patient feels pain; there is, then, disease of some kind at this point, and it is here that we are to search for the origin of the fistula. From all these signs we are warranted in affirming the existence in this case of an irregular focus of inflammation, one prolongation of which occasions the cutaneous induration in the neighborhood of the fistulous orifice; we have here the indication of a secondary pus burrow.

What can be the cause of this kind of fistula, unless it be a lesion of the bone? But what is the nature of this bone disease? This must be determined before a rational prognosis can be made, or a suitable treatment instituted. You are aware, gentlemen, that the question of ossifluent abscesses has become quite a question of late, by reason of recent discoveries in

pathological anatomy, which enable us to affirm their tuberculous nature, and by reason of the modifications which their treatment has undergone. What, then, is the lesion of the bone? We cannot go astray in assuming it to be tuberculous. The osseous tubercle, which is always found when it is sought for, is ordinarily developed without any traumatic cause. You see at first, under the periosteum, a mass of embryonal cells which destroy the osseous trabeculæ; then, at the end of a certain time, you are sure to find opaline granulations of tubercle in the midst of this mass. Lastly, these tubercle granula degenerate, become yellow, caseous, liquefy, and form a tuberculous abscess. The abscess, however, does not always follow the lesion, may not pass the stage of caseification, and in this case resorption is still possible. Whenever a lesion of this kind is produced in a bone, the latter institutes a sort of protective process: around the tuberculous nodule an inflammation is set up, a zone of condensing osteitis, which establishes a barrier between the healthy and the diseased parts.

But it must be admitted that oftener an abscess forms, the periosteum is elevated and ulcerates, and pus invades the neighboring cellular tissue; the abscess sac then enlarges, and soon approaches the surface. To a small osseous lesion may correspond a vast abscess, connected with the bone by a narrow neck, and containing several quarts of pus.

You have certainly seen those vast abscesses which are consecutive to Pott's disease of the spine; these are perfect types of ossifluent abscesses. We have not to do merely with the bony lesion and the pus which it secretes. This lesion is often too insignificant to explain these great collections of matter; but there exists also an anatomical reason which enables us to comprehend the often prodigious development of these abscesses. This reason is the texture of the sac which contains them, and which in these particular instances truly merits the name of *pyogenic membrane*. It is a matter of common observation that when these abscesses open the fistulous tracts, the neighboring tissue-detachments and the surface of the diseased bone are covered with fungosities; a sort of tomentous membrane fills all the cavities and secretes the pus, and this explains why these lesions so obstinately persist, despite energetic treatment. What we surgeons are most apt to see is the relics of these abscesses, as in the case of our little patient.

The anatomical constitution of this pyogenic membrane explains the prolonged suppuration. It is especially to the studies of Lannelongue, and of Koester, that we owe the knowledge we possess of this subject. This membrane is formed of three generally quite thick layers thus superposed: 1. An internal layer in relation with the pus, which is of fungous character, being constituted of fungous granulations. 2. More deeply still, a layer of gray tubercle granula. 3. A fibrous, or limiting membrane. Hence, it is easy to understand why irritant injections do not succeed in completely destroying this new formation; it is only by the red hot iron, or by curetting and scraping, carefully and thoroughly done, that we can hope to effect the disappearance of this membrane and thus obtain a cure. This method of treatment is applicable to all cold abscesses.

Those pus-burrows, those glove-finger prolongations which characterize this kind of abscess, find an explanation in pathological anatomy, for upon this membrane there are little *culs-de-sac* which seem to be the starting point of future prolongations. Hence, arises the necessity, when you curette an abscess, of taking the utmost pains not to neglect any of these *culs-de-sac*, and to scrape out all the prolongations; unless you do this you will have your work to do over again. These lesions are unquestionably of tuberculous origin; histology proves it, clinical practice confirms it, and the constant presence of the tubercle bacillus may be regarded as infallible evidence of it.

What shall be the prognosis of these abscesses? and what would become of this lesion if left to itself? It is undoubtedly true that now and then an abscess of this kind has got well of itself, especially when it originates in the walls of the pelvis; but such cures are very exceptional, and only come about after a long time. I have, however, seen a few of these abscesses get well after one or two aspirations.

In order to obtain a speedy and favorable termination, surgical intervention is required. Bear in mind that it is a bad plan to leave a patient who is suffering with ossifluent abcess too long exposed to the evils of suppuration; for, by reason of the nature of the disease, you would have reason to fear a general infection starting from this local tuberculosis, and you might ultimately see your patient carried off by pulmonary phthisis, or tuberculosis of the peritoneum. In the case of our young man, I do not think that we can look for a spontaneous cure this hardness in proximity to the fistula;

this violaceous and indurated swelling, prove to us that the affection is far from the period of decline, and rather on the increase. Moreover, the patient is in bad condition physically, and is a fit subject for the spread of the tuberculosis, and this would be a sufficient reason why I should surgically interfere. Considering the location of the abscess, we cannot employ the antiseptic dressing in all its rigorousness; but I will perform the radical operation by means of the thermocautery, and I will cauterize deeply all parts of the fistulous tract, in order thoroughly and completely to destroy the membrane which lines it. After having previously removed all the fungosities, as soon as I shall come down upon the bone, I will make use of the curette in order to scrape away all the diseased tissue as far as the indurated zone. As there will be bleeding points in our wound, I will afterward, as a dressing, pack it with tampons of iodoform gauze.

I have just given you in connection with our young patient the history of ossifluent abscesses in general. We have in our wards a female patient whom I shall now present, who will illustrate more especially osteitis of the pelvis, and its pathogeny. This woman is now twenty-seven years of age, but it was at about the age of thirteen or fourteen years that she experienced the first symptoms of the disease which to-day brings her to our wards. At this time of life she fell, striking the region of the pelvis; the traumatism was quite slight, since, at the present time, she cannot specify exactly the point that was contused. Three months afterward, there presented itself in the right inguinal region a little indolent swelling, which became fluctuating, and burst, giving issue to a certain quantity of pus; this abscess was then transformed into a fistula which persisted for a number of months, and finally got well of itself. At the end of a certain time, as a result of too fatiguing work, this fistula broke out anew, and another one like it was produced by the same mechanism in the region of the left groin. Meanwhile the patient married, and had a child; these fistulæ continued to cause no serious harm, appearing and disappearing from time to time, but never entirely getting well. For some time past, and since the commencement of a second pregnancy which is now going on, there has been an aggravation of the local disease. Quite severe pains have been felt about the upper and posterior part of the right hip where a new abscess has formed, ending, like the previous one, in the production of a fistula. The one on the left side, which for a time was healed, has broken out anew. A probe introduced into these fistulæ penetrates to a considerable depth, but does not strike bare bone. The palpation of parts in the vicinity of these fistulæ discloses a good deal of swelling, and at the same time a fixed *point douloureux* on the right side in the neighborhood of the os pubis. The finger introduced into the vagina detects the same swelling, and elicits the same pain when high pressure is made on the lateral wall of the same side. But this is not all; if the pressure is continued for a certain time, it gives rise to the flow of a quantity of pus by the newly-formed fistula. The rectal touch does not elicit any similar symptom. The pressure of the finger on the left lateral wall of the vagina does not at first give rise to any symptom worthy of note; when, however, it is made with considerable force, it also determines a painful sensation in the region of the pubic bone of the same side.

These symptoms undoubtedly point to a lesion of the pelvis, probably of its pubic portion. We may even be sure that the pus which is formed in the diseased foci has made for itself a passage through the soft parts of the vicinity, and has finally pointed at quite a distance from its source.

Such are the lesions with which our patientis afflicted. What is the prognosis and what shall be the treatment? Such are the questions now before us. But, before taking up this part of our subject, permit me to indicate to you, in a few words, the pathogeny of this variety of osteitis, which has been for several years the subject of numerous works, of which you will find a summary in the recent excellent thesis of Gouilloux, pupil of Ollier, of the School of Lyons. The ossification of the different pieces which enter into the composition of the os innominatum takes place by two successive developmental processes. In the first period, the os innominatum is constituted by three distinct segments, corresponding to the ischium, the pubes, and the ilium, which converge toward the centre of the cotyloid cavity, and are separated from each other by connective cartilage. At about the age of ten or twelve years, this cartilage ossifies, and the bone is constituted in its essential characters. But about the age of thirteen or fourteen years, a little earlier in females than in males, there appear, at the periphery, complementary points of ossification, separated from the bone by a special connective cartilage. These are the pubic points, for the internal extremity of the pubis, the iliac points for the crest of the ilium, the ischial points for the

tuberosity of the ischium, the ischiatic points for the ischiatic spine, and lastly the posterior iliac points for the postero-superior spine of the ilium.

Now, since the spontaneous lesions of the bone habitually develop in points which border on the connective cartilage, this being the most active seat of osteogenesis, the following results are sure to happen: During the first twelve or thirteen years of life, the bone diseases of the pelvis localize themselves always at the centre of the bone—that is to say, in or around the cotyloid cavity. You know, in fact, that up to this time of life coxalgia of bony origin is very frequent, while very rare after this period. From the age of fifteen years, things take place differently. When the pelvis becomes the seat of an idiopathic osteitis, this always, or almost always, develops in the peripheral parts, in certain well-defined spots, which are none other than the points of ossification of which we have just spoken. There are, then, osteites of the internal part of the pubes, of the tuberosity of the ischium, of the crest of the ilium, of the spine of the ischium, of the posterior-superior spinous process of the ilium. Add that it is not rare in these osteites, at least at the onset, to find a sequestrum which is constituted in its totality by the osseous part, the epiphysis, not yet united to the rest of the bone. Unfortunately, matters do not always rest there. The affection does not always remain localized to the epiphysis; it may extend to the diaphysis, and to the periosteum, which covers it, so that, limited at first, it becomes general, and in time acquires a gravity which it did not have at first.

You see at once, without the necessity of my longer insisting thereon, the importance of early interference, if one would prevent the extension of the disease. A little operation performed in time often suffices to accomplish the radical cure of a lesion, which, if it goes on, cannot be benefitted by the most extensive and formidable operation. However this may be, these osteites, when once developed and left to themselves, undergo evolution in two ways. Sometimes they take on an acute march with inflammatory phenomena of considerable intensity, vast detachments of the periosteum, and grave general symptoms of a typhoid character. This train of symptoms, which is none other than that of infectious osteo-myelitis, designated under the name of *typhus of the members*, is not now under consideration; this is not in fact what our patient has been suffering from. At other times, the disease has a less rapid course and one fraught with less anxiety. The inflammatory phenomena are moderate for a long time; the lesions are localized, giving rise to pains having their principal seat at the diseased point, but likely to radiate to different parts. In a city patient, suffering from this same affection, and in whom I had to remove the spine of the ischium, the pain was felt chiefly along the course of the sciatic nerve, and that person had in fact been treated for more than a year for ordinary sciatica. The same painful irradiations may affect the crural and obturator nerves when the disease is seated in portions of the neighboring bone. At the end of a certain time, the pus, which forms in the diseased focus, tends to make its escape externally. Almost always the pointing occurs in a spot which is at considerable distance from the seat of the pus formation. We must, however, make exception in this case of the pus which comes from lesions of the crest of the ilium; this part being subcutaneous, the abscess points immediately over the spot where pus is formed.

Things are quite different when the pus comes from some of the other regions of the innominate bone. The pus has been known to open a way into the vagina, the bladder, the rectum, into the septa of the crural muscles, sometimes as much as ten or fifteen inches from its starting point. I have even seen an abscess of this kind open in the neighborhood of the popliteal space. These are facts of an uncommon character, of which, however, you must be cognizant if you would avoid gross mistakes in diagnosis.

The young girl from whom I removed the spine of the ischium, and of whom I have just spoken to you, had at the time I operated on her, a fistula in the neighborhood of the anterior superior spine of the ilium, and another in Scarpa's triangle. At three different times she has passed pus by the rectum; for six months the abscess emptied itself into the bladder. In cases like this, authorities have sometimes seen fistulæ of like nature complicated with the passage of a sequestrum into the bladder, and this sequestrum has finally become the nucleus of a veritable calculus. When the fistula is not too far away from the diseased point, and can be explored, you will sometimes find simple sequestra surrounded with fungosities. I have already spoken to you of these sequestra, and have shown you that such cases are the most favorable—sometimes so favorable that the sequestrum may be eliminated spontaneously, and the patient will get well without the necessity of surgical interference. At other times, the probe comes upon a bony surface

in continuity with the rest of the bone; this surface is bare, friable, bleeding at the least touch, and, if exposed, you observe that the diseased part extends a great distance: it has been found to occupy the half of the ilium.

The prognosis is in relation with the extent of the lesion. Benign in mild cases, since the disease may get well of itself, it is very grave and finally entails death when a great extent of the bone is diseased. It is true that, in the latter cases, the patient sometimes preserves for a long time the appearances of health. I need only refer you for proof to the patient who is the subject of my lecture. Her disease, which began about the age of fifteen years, constantly progressed for thirteen years; and, nevertheless, she married, had one child, and became again pregnant. But this favorable condition cannot last. Under the influence of the interminable suppurations to which these patients are subject, there is developed, sooner or later, a special cachexia due to exhaustion, to amyloid degenerations of the liver and kidneys, as well as blood poisoning from stagnation and absorption of pus; and, finally, the patient falls into marasmus and dies.

The treatment of these lesions is dominated by this fact, resulting from what I have just told you, that early interference is necessary, while the lesion is limited to the epiphysis, and is manifested by the presence of a sequestrum, which is the epiphysis itself. Our first patient, as I have told you, was in this condition; I removed the part of the ischium which was diseased, and doubt not that the event will prove that a radical cure was effected. It will not always be necessary to attempt at once the search for the diseased bone. You would be perfectly warranted, when in the presence of a recent abscess, in restricting your efforts at first to a simple puncture with the aspirating needle, which you may even repeat several times. I have had the opportunity of observing four patients who were plainly affected with these varieties of osteites, and who have been radically cured after four or five punctures. In two of them the lesion was seated on the rami of the pubes; in one it was in the iliac fossa; in one in the posterior-superior spine of the ilium.

This simple method of treatment, however, ought not to be continued indefinitely; and if at the end of a certain time, which should vary according to the gravity of the lesion, no amelioration is produced, you should cut down upon the seat of lesion and remove any diseased or dead parts. Once it was the custom to wait till the abscess burst of itself; it is no longer necessary to exercise this caution, now that with Lister's antiseptic dressing, we are able to insure the patient against the dangers of that septic fever which formerly was an almost certain accompaniment of the spontaneous opening of these osteopathic abscesses.

When the abscess has its origin internally in the iliac fossa, it has been proposed to attempt its exploration by trephining the iliac bone. This is an excellent means; moreover, in certain cases it is the only means which satisfies the indications of giving sufficient access to the focus of disease. I need not say that if, instead of a loose sequestrum, you should come upon a spot of carious bone without precise delimitations, you should remove all the diseased tissue. In cases of this kind, Ollier has performed ablation of portions of bone which were truly enormous, and has had only good results. You should bear in mind, furthermore, that the operation is of benefit to the patient, even when it is impossible to remove all the diseased bone. There is, in fact, always an advantage in being rid of a suppurating surface of bone of considerable dimensions, whose presence is a powerful source of enfeeblement and cachexia.

The free opening of all pus tracts and pus burrows in a downward direction, so as to facilitate the flow of pus, also renders great service to patients, even when you cannot scrape away or remove the diseased bony tissue.

It is these latter considerations which have induced me to propose interference in the case of our patient. When she shall have completed the puerperal period, I shall undertake an operation in search of diseased segments of bone, and any which may be found shall be removed as thoroughly as possible. I do not dare to hope that I shall thus succeed in wholly arresting and suppressing the disease, and thus curing the patient; but what I am sure of is that I shall notably ameliorate her condition and prolong her life, while making it much more comfortable.

—The St. Alban's Hospital, at St. Alban's, Vermont, was burned on Sunday night, January 12, and two out of eight patients were suffocated. The fire was discovered in a closet in the kitchen, and soon got beyond control. There was no male help, and no special provision had been made against fire.

COMMUNICATIONS.

FLAT ROCK AND HENDERSONVILLE, NORTH CAROLINA, AS HEALTH RESORTS.

BY ALLARD MEMMINGER, M.D.,

PROFESSOR OF CHEMISTRY AND HYGIENE IN THE STATE MEDICAL COLLEGE OF SOUTH CAROLINA, CHARLESTON, S. C.

As the influence of climate on phthisis and its allied affections just now engross so much of the attention of professional men, and especially the climate of western North Carolina, it may not be out of place to bring to the attention of health-seekers a little summer resort which is as yet unknown, but which I hope before long will be as conspicuous in the eyes of the public and those seeking a health resort as Asheville and her environs—I refer to Flat Rock, North Carolina, situated on the Asheville and Spartanburg Railroad, which can be reached from New York in twenty-seven hours, and from New Orleans in twenty-eight.

At present, Flat Rock consists of a settlement made up of many well-to-do families, who have for more than half a century been in the habit of spending the best part of the year in pleasure, recreation, and recuperative pursuits.

This place is peculiarly situated and well fitted by nature to be a health resort. The climate is mild and temperate; the soil, although unfertile, presents to the sanitarian those conditions upon which the healthfulness of a place depends—that is, comparative dryness of surface soil, great depth of the ground-water, and slight fluctuations between the ground and surface waters.

Flat Rock, North Carolina, is situated on the Asheville and Spartanburg Railroad, 2226 feet above the level of the sea, forty-nine miles from Spartanburg, South Carolina, and twenty-two miles from Asheville, North Carolina. It is surrounded by mountain ranges, which are at distances sufficient to keep off and break the cold blasts of winter, and not sufficiently near to create droughts or to change the number of sunshine hours in our short winter days. The average height of these mountains may be placed at 1000 feet, although the many peaks of these mountain chains often rear their proud and lofty heads as many more.

Two miles from this favored spot lies Hendersonville, a picturesque little village of eight hundred or more inhabitants, but which in summer time for a short while contains as many more. This town has, in my opinion, more claims to being a health resort than is generally conceded to it by the public. It is situated on the same plateau as is Flat Rock, and has a similar climate and soil, barring of course, the impurities incident to a larger population and a smaller area. Surrounding this village are the summer residences of wealthy families, which, having determined to make this part of North Carolina their summer home, have located on the boundaries of the village, so as to enjoy the advantages incident to being near a town. Taking all things into consideration the climate and soil of these two places are alike. Situated thus between mountains which are sufficiently remote not to be obstructive, Flat Rock offers to the invalid many advantages over places situated more in the heart of the mountains, and which do not offer so many facilities for excursions by foot and by carriage. The drives are good, the walks well shaded, and the roads so graded—or rather the natural grades are so moderate—that those recovering from serious attacks of illness find it no hard task to take either a morning stroll or an evening walk.

This resort, as before said, being originally planned by wealthy residents of the seaboard, has naturally partaken at all times of their refinements; and could this locality be brought more conspicuously into notice, I am quite sure that to place a large and fine hotel in this "land of the sky" would be an enterprise likely to be crowned with financial success.

Situated in the heart of this picturesque little settlement, almost on the banks and in view of one of the most beautiful of artificial lakes, stands the church, which happens to be Episcopalian, but in which all denominations meet and pour forth their humble prayers on Sunday, devoutly kneeling. Around this church stand the sentinels of the past, which show that the Angel Azrael has dealt kindly with this little flock.

The geologic formation of this place belongs to the Eozoic period, and comprises the Huronian, Labradorian and Laurentian systems; the soil is sterile and unfertile, and the drinking water is as free from impurities as the soil is free from fertilizing ingredients; the springs are bold, cold, sparkling and as clear as a crystal, and the wells which I have repeatedly seen sunk, and of which I have more frequently drunk, may be characterized as good and wholesome drinking water, free from lime and magnesia, and vieing in excellency with the springs just mentioned.

It seems to me, in view of these facts, that diseases contracted in this section can never be fairly attributed to emanations from the soil, or to the character of the water used for drinking purposes. On the contrary, in every case of typhoid fever or kindred "filth," affections, which has come under my notice, the cause has been clearly traceable either to defective drainage and a general and total disregard of sanitary laws, or else to water pollution.

If we glance a moment at the climatological conditions of this place, I think we may safely say that it is entitled to as high a place in our estimation as a health resort as is Asheville, twenty-two miles distant. This is not because it is peculiarly exempt from moisture for the whole year—which I have always doubted was true of Asheville and western North Carolina in general—but from the fact that the other conditions which go to make up a good climate and a safe health resort are fully attained, namely, a dry soil with a *low* water level; small fluctuations in the ground water; good mean temperature for the year; plenty of sunshine; a sufficiency of ozone, and no emanations from the soil which are prejudicial to health.

I do not mean to say, as some have said, nor to be understood as saying, that this climate combines all that is essential for all classes and cases of consumption; but I do mean to say that in those cases of phthisis in which the absolute amount of moisture is not the main consideration, but in which plenty of outdoor exercise in the sunshine and in an air of an exhilarating and stimulating character and free from dust and organic impurities is needed, a most beneficial effect may be expected from residing here or in some place similarly situated.

I must take exception to the assertion, sometimes made, that consumption is not found in western North Carolina. I have frequently met with it here, as must inevitably be the case elsewhere if we take the modern view of the pathology of this disease. I also doubt that it will always be arrested in this section, although I agee that many cases of catarrhal phthisis are improved and rendered less severe here. The class of cases which I have so far seen most benefitted have been of the catarrhal type and in the first stages. I can affirm from a general and extended experience of many years that an abundant supply of sunshine, accompanied by an exhilarating soft and bracing atmosphere, free of almost all kinds of impurities, is attained in this latitude. When, therefore, these adjuvants are desired, either in cases of consumption or in any other affections, I do not think that more could be accomplished save in the far West, or in Arabia, more distant still.

I append a tabular report of the meteorological condition of this place and of some others, and I think, after a careful review of the figures, that we can safely say that none are entitled to the name of dry climate save Denver and Cheyenne. In many respects the Flat Rock summer climate corresponds to the Jacksonville winter climate, enjoying most of her advantages and none of the disadvantages incident to winter.

The altitude, together with the moisture, renders the air soft and balmy, and we have thus the good effects of a Florida climate coupled with the exhilarating and tonic effects of the air of an elevated region. The nights are cool and pleasant, and the moisture, which with the increase of barometric pressure at a lower altitude would render the air close and heavy, is at this altitude changed into a light and soft atmosphere, soothing, invigorating and strengthening to the nervous system, instead of one debilitating and enervating.

	Mean Annual Temp.	Highest Temp.	Lowest Temp.	Mean Relative Humidity.	Average Rain fall in inches.	Mean Max. Temp.	Mean Min. Temp.	Number of clear days.	Elevation above sea level in feet.
Flat Rock	62.5°	87.5°	3°	*77.8	40.14	—	—	—	2,226
Asheville	54.1°	94.0°	6°	70.3	42.55	64.3°	46.0°	259.0	2,250
Charlotte	60.6°	101.0°	5°	66.7	54.10	69.7°	51.9°	251.8	808
Charleston	66.2°	103 0°	13°	73.1	59.91	73.1°	60 2°	274.8	52
Jacksonville	69 5°	104.0°	19°	71.2	55.31	77.9°	62.2°	280.0	43
Atlanta	61.7°	99.4°	13°	67.4	56.23	69.4°	52.9°	260.1	1,129
Denver	49.3°	105.0°	29°	46.5	14.99	61.5°	37.4°	309.3	5,204
Cheyenne	44.1°	100.5°	38°	52.2	11.07	56.2°	30.9°	302.9	6,105

* The mean relative humidity is too high, being calculated from two few months. It would correspond to that of Jacksonville if computed for the year. The rain fall is also possibly a little too low.

A CASE OF NORMAL OVARIOTOMY.

BY LLEWELLYN ELIOT, M.D.,
WASHINGTON, D. C.

The following is the history of a case upon which the late Dr. Johnson Eliot operated, and it is reported on account of the age of the patient:

M. F., white, 58 years old, born in Ireland. Previous history negative. Her menstrual periods have always been regular; the last one occurred ten years ago. She has had seven children. Eight months previous to the operation she noticed that the abdomen was gradually enlarging, and, as she expressed it, she felt as if she was pregnant. In February the enlargement increased rapidly and operative procedure was deemed advisable. On March 14, 1883, the patient was etherized, the abdomen washed with a solution of carbolic acid, and under the carbolic spray an incision four inches in length was made along the linea alba; the sac was exposed and its contents evacuated. An attempt was made to use the Spencer Wells trocar, but, owing to the colloidal character of the fluid, this was impossible; so the contents were turned out with the hands. About a quart of very dark-green fluid gushed out. The sac was situated on the right side, was multilocular, and was estimated to weigh twenty-eight pounds. The sac was drawn out of the abdominal cavity and held with a clamp; the pedicle was tied with carbolized Chinese silk, divided and dropped into the cavity. After arresting bleeding and thoroughly drying the parts, the external wound was closed with five carbolized silk sutures, the whole covered with carbolized lint and held in place by bands of adhesive plaster. Reaction was good. A hypodermic injection of morphia sulph., gr. ¼, was administered and the patient put in bed. At 8 P.M., the temperature was 99⅗°, pulse 92; the pupils were contracted; there was no pain. She was ordered warm milk diet, and five minims of tincture of aconite (Fleming's). At 10 P.M., the temperature was 99⅖°, pulse 84; no pain; morphia sulphate, gr. ¼, given hypodermically.

March 15, 6 A.M. Temperature 99⅘°, pulse 92; no pain; warm milk diet continued. At 10 A.M., she had rumbling in the bowels, but no pain; morphia sulph., gr. ⅜, given hypodermically; and tincture of aconite, ♏ iij. The patient has urinated four times since the operation, without pain or difficulty. 6 P.M. No pain; has nausea. Ordered tincture of aconite, ♏ iij, with morphia sulphate, gr. ¼; carbolic acid (No. j), gr. ½. 12 P.M. Temperature 100⅖°, pulse 92; no pain, no nausea; has slept, and has urinated without difficulty or pain.

March 16, 2.15 A.M. Temperature 101⅕°; pulse 94, strong and full; skin hot and moist. Ordered tincture of aconite, ♏ ij. Feels very well, except an emptiness of the stomach; no nausea. 12 M. Temperature 100°, pulse 94; complains of itching about the wound.

March 17, 2.15 A.M. Temperature 100⅕°, pulse 90; skin moist and soft; complains of no uneasiness. 7.15 A.M. Temperature 99⅕°, pulse 88; passed a good night. 12 M. Temperature 99°, pulse 84.

March 18, 10.25 A.M. Temperature 98⅘°, pulse 80; passed a good night. Dressings changed. There has been no discharge; wound closed; no tenderness; milk and boiled rice diet.

March 19, 10 A.M. Temperature 99⅖°, pulse 84. 9.30 P.M. Temperature 100, pulse 78; morphia sulphate, gr. ⅙, hypodermically.

March 21, 22, 23. No observations taken; morphia sulphate, gr. ⅛, given each night, as before.

March 24. Bowels moved.

March 25. Sutures taken out, the central one being followed by a few drops of blood. This blood was caused by a slight tear in the integument. No pus was present, no pain complained of, and no tenderness on percussion.

March 28. Patient sat up. From this date no observation was recorded, as the progress of the case was unattended by any change calling for attention. She soon resumed her household duties, and has continued well. She has a small ventral hernia at the lowermost part of the cicatrix, but it gives her no uneasiness.

EXCESSIVE MEDICATION.

BY O. L. ABBEY, M.D.,
WATERFORD, PA.

How many of us in the first years of our practice medicate too much? We are not always quite sure of the disease, but sometimes think we are, and give medicine expecting to shorten its course or to abort it. In after years we treat similar cases with one quarter the medication we then used, and think a great deal of our former medication was not indicated. Many practitioners give compounds which are absurd. I can call to mind following the advice of consultations, when there were two or three compounds

suggested, each compound containing four different ingredients, and the patient getting as many as twelve different medicines. Now, if these were all good for the patient, why would it not have been wise to try two at a time? I have been called in consultation where, before I was called, the physician had tried everything in the materia medica indicated for that disease.

When I was asked if I could suggest anything different, I wondered the patient could withstand so much. We laugh at the homœopathist giving, Ac., Bel., or Mercurius, No. 10, No. 15, etc., at intervals of ten or fifteen minutes. But if some of the compounds we prescribe every three hours were separated and given singly one would be administered quite as frequently. There are times when the friends of a patient feel that they are not doing much for a sick person if the medicine comes only at intervals of one and a half hours. In such cases I would extemporize some simple thing to fill in and keep them busy. My best success in treating fevers has been where I medicated very little.

If a drug does not do good in a certain case the patient fares better without it, for it may do absolute harm. This is especially true in acute cases. How many men have used spirits of nitrous ether for some time before they found out that, in kidney troubles, where there is acute or chronic inflammation, it does absolute harm; and that it is useful in kidney trouble only when the kidneys need a stimulating diuretic.

Of course in this day, when everything is run through at railroad speed, a patient's friends want to see something done most of the time. This is especially true in small towns, where physicians dispense their own drugs, where there is no pharmacist's bill to pay, and where the friends may be believers in homœopathy, such friends are always ready with their advice, and free to say that their doctor gives them Ac. and Bel. or Kalium; and if the pain is in the right ovary they give them Apis. and Bel., and if it is in the left ovary they give Lach. every ten or fifteen minutes. These exigencies must be met; but let it be done with simple things, and by attending to the hygiene of the room, and as much as possible by means of local applications, instead of drugs.

Last winter I was confined six weeks with acute bronchitis. I ran the scale on aconite, gelsemium, ipecac, muriate of ammonia and squills; but notwithstanding all these remedies it took six weeks for me to get well, and I received benefit from only two things: veratrum viride and Dover's powder. I think if I had kept my bed and taken nothing but veratrum viride at first, and followed it with the Dover's powders, I would have got along just as well and perhaps better. I have treated severe cases of acute pneumonia with veratrum viride, followed by ipecac, this being the only two medicines I have used. I have no doubt that in many cases of fever, where so much medicine has been given, nature effected the cure, and the patients recovered in spite of the treatment. Many cases of fever will do well with a good diuretic, given until the fever abates, and followed by quinine. Giving a medicine for every symptom arising in the course of a disease is too much like the plan of the homœopaths who give different remedies for pain in the right or left ovary. This may display good theoretic knowledge; but is it good for the patient? I knew a physician, who died twenty years ago, who had an extensive practice in the country. He had a great reputation for treating fevers, and his practice was so extensive that often he could see his fever patients only once in every three days, and of course his medicine was not changed during that time. Usually his patients had only two things to take. He medicated but little, and his success was above the average; among his strongest points was the fact that his good judgment told him what not to give. This is one great secret of success in the practice of medicine.

I think that one reason why so many intelligent people are homœopathists depends upon the fact that they think that, if their medicine does not do any good, it does no harm. When I think of the many medicines used in the present day, it seems to me important to ask: Is the percentage of cures of acute diseases any larger now than it was twenty-five years ago, when but a small part of the remedies we have now were known or administered?

—An official notice has been published by the Berlin *Deutsches Tageblatt* of Nov. 17, which gives some information regarding "Warner's Safe Cure." The announcement describes this preparation as a brown liquid in flat bottles, containing about one pint, which has been for some time recommended for kidney complaint, and sold at the price of $1.00 a bottle. The official chemical examination of the same, together with the declaration of a Berlin apothecary who introduces it, makes known that its essential ingredient is American wintergreen, and that the bottles are, at the highest valuation, worth only 50 cents each.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, February 2, 1888.

Thos. M. Drysdale, M.D., in the chair.

Dr. B. F. Baer presented the specimen, and read the report of a

Case of Non-Papillary Intra-Ligamentous Cyst,

in which he had enucleated the entire tumor in the right broad ligament, but only the lining membrane of the cyst in the left broad ligament.

Sessile tumors, whether cystic or solid, are always more or less dreaded by the operator, because of the greater difficulty and danger attending their removal, and also because, in the case of sessile cysts, the result as to the permanent relief of the patient is less certain than where the tumor has a pedicle. Clinically and pathologically, therefore, these cases are of great interest and importance. Pain and hemorrhage are the important subjective symptoms. The former is usually present, sometimes in great severity; the latter is at times alarming in the quantity of blood lost and in the frequency of its recurrence. This is not surprising when we consider the close relation which these tumors sustain to the uterus and to the other pelvic organs and tissues. The wedging and pressure which result from the growth of the tumor in the limited space produce great congestion of the blood-vessels from stasis. The uterus becomes enlarged and softened in consequence, and metrorrhagia follows; but the hemorrhage is conservative to a certain degree in relieving the distended vessels, probably averting rupture of a vein in the broad ligament or in the tumor. The pain which results from the tension and stretching of the nerves involved is also relieved or modified by the depletion following a free hemorrhage from the womb. But the flow once started, does not always remain within the conservative line; it sometimes becomes uncontrollable, and results in acute and serious anemia.

According to Doran, sessile cysts which arise from the hilum of the ovary or from the Wolffian relics in the broad ligament are usually papillomatous; but that non-papillomatous sessile cysts infiltrating the broad ligament are not infrequently met with is shown by the following statement from that author: "In twenty-four cases where I assisted at the operation, sessile cysts infiltrating the broad ligament were removed, more or less completely, but their origin could not be ascertained; none of them contained glandular growths, most were multilocular, but papillomatous growths did not exist." (Tumors of the Ovary, etc., p. 68). Further, the ordinary pedunculated multilocular cyst of the ovary sometimes contains papillomatous growths, the result possibly of stray Wolffian relics. I have presented at least one such specimen to this society, and I have seen others. On the other hand, the multilocular ovarian cyst without papillomatous material has been found, in rare instances, to have invaded the hilum and broad ligament in its growth. Doran records two such cases. He says: "I have seen two cases where a sessile cystic tumor of the ovary was removed, and this proved to be an undoubted case of glandular cystic disease, invading the hilum and the broad ligament." The case which I here report is probably another instance of this pathological anomaly.

Mrs. X. was sent to me by Dr. O. H. Adams, and entered my private hospital in April, 1887. She is 32 years of age, married, and has had three children, the last two (twins) eight years ago. Following her last labor she had puerperal mania, which necessitated her confinement in an insane asylum during four months. Two years ago she began to have attacks of sharp pain in the right ovarian region, radiating to the groin and down the anterior portion of the thigh. The pain was intermittent in character and cramp-like, lasting hours at a time, and was usually followed by a purulent, fetid discharge from the vagina, which would afford her great relief. At other times the attack would end with a profuse metrorrhagia, which would leave her pale and weak, but free from pain. About two years before coming under my care, she first noticed a "lump" in the right groin, which has gradually increased in size. Sometime after, she noticed a similar growth above the left groin. She was considerably emaciated and looked very ill. Examination revealed a tumor as large as a child's head in the right iliac region, and a smaller one in the left ovarian region. The tumors seemed to be fixed in the pelvis, and to have a broad base of attachment; they were immovable below but mobile above, and semi-fluctuating. Vaginal examination showed them to be so deeply attached in the pelvis and so intimately related to the uterus, that I was

unable to complete my diagnosis without anæsthesia. The patient was therefore placed in bed and ether administered, when it was found that the uterus was elevated by the tumor on the right side with which it was connected. There was evident fluctuation, though the tumor was thick-walled and very firm, almost hard. The lower surface occupied the position of the broad ligament at the side of the uterus. The same condition existed at the left side, but to a less degree. I diagnosticated sessile cystic disease of both ovaries or broad ligaments, and advised immediate operation, to which the patient gladly consented.

On April 13, 1887, I proceeded to operate, being kindly assisted by my friend Dr. Daniel Longaker. When the tumors were exposed, they were found to be so closely connected with the womb, that they seemed to be one with that organ, which rested as a wedge between them. The Fallopian tubes extended outward over the upper surface of the tumors, while the broad ligaments and the greatly distended veins of the pampiniform plexus were expanded so as to apparently envelop them, the whole presenting a dark, purple appearance, which was not at all reassuring. After separating some slight adhesions on the posterior aspect of the larger tumor, and rolling it forward, the nacreous surface common to the multi-locular ovarian cyst was exposed to view. Selecting a spot on this free surface because it was less vascular, I now plunged a trocar into it, when about two pints of a tarry-looking fluid drained away. A more thorough investigation, which the diminished size of the tumor now afforded, showed it to be adherent to the cæcum also. Previous to beginning the enucleation, I passed a long blunt needle charged with a double ligature through the expanded broad ligament at its least vascular portion, between the uterus and the tumor, and as far below the Fallopian tube as could be done with safety. One side of the ligature was then drawn up and tied close to the uterus, including within its grasp the tube and vessels. Thus insured against hemorrhage from that source, I now cut through as far as the ligation extended, and continued the enucleation down to the base of the tumor, and then outwards, finally separating it from the head of the colon. There was some bleeding from the numerous veins which were broken, but this was readily controlled by catch-forceps and ligatures. Attention was now given to the tumor on the left side. This was found to be deeply imbedded in the pelvis and firmly fixed to the uterus, Fallopian tube, descending colon and rectum. The upper surface was covered with a network of distended veins, some of them as large as a quill. Enucleation of this tumor seemed too hazardous, and hysterectomy was out of the question; for to do the latter the tumor must first be dissected from the colon and the pelvic floor, which was not practicable. I determined, therefore, to evacuate the contents of the cyst by aspiration and then to shell out the lining membrane, or, failing in this, to insert a drainage-tube into it. But, while endeavoring to find a position for puncture, my finger passed into the tumor low down on the posterior border of the broad ligament. Instantly the parts were flooded with a tar-like, semi-fluid substance similar to that which had been evacuated from the cyst on the right side. This was removed as quickly as possible by sponging. I then passed my finger through the opening which I had thus accidentally made, and after a careful and gentle dissection succeeded in removing the entire secreting surface of the cyst. Blood was now flowing from the small valvular opening in the broad ligament, but as it was apparently venous I hoped to check it by compressing the now flaccid folds of the broad ligament. For this purpose several large sponges were inserted and external pressure made upon them while the abdominal sutures were being placed. The sponges were then removed. There was still a slight flow of blood, but as it was doubtless only a venous oozing I concluded to close the wound and trust to pressure and the drainage-tube. The patient was placed in bed and the tube carefully watched. During the next two or three hours several teaspoonfuls of quite bloody serum passed through it; after forty-eight hours the tube was removed.

This patient made a slow, but good recovery, and went home six weeks after the operation. She has been entirely relieved of her former sufferings, and the loss of weight and strength have been regained.

Dr. Wm. Goodell reported

A Case of Splenectomy.

Mrs. R., aged 40, had chills and fever in early life, but after her marriage, 18 years ago, she removed to a healthy country town and had no return of the disease. She has had two children, the youngest 7 years ago. At this labor she had a serious flooding and was confined to her bed for six months from excessive prostration. Since that time, she has never been well, being weak and miserable. Her monthly periods were always free

and generally painful. Last March she had a very severe attack of what her physician called malarial fever, and her life was threatened by repeated attacks of hæmatemesis and hæmoptysis. A sore tumor was now discovered, which was pronounced to be a uterine fibroid, and she was sent to Dr. Goodell. He found the womb pushed low down and retroverted by a solid tumor, which started from the region of the right ovary and ran diagonally towards the splenic region. It entered the pelvis so low down as to cause bulging of the anterior wall of the vagina. The womb seemed to be independent of the tumor, for the former could be moved about freely with the sound. Yet when the tumor was pushed upwards, it conveyed motion to the womb, drawing it also upwards. The tumor was always painful, and the complexion of the woman was markedly cachectic. The diagnosis made was sarcoma, either of the right ovary or of the omentum.

At the operation a very long incision was needed, reaching not quite up to the ensiform cartilage. The tumor was of a dark purple color and was attached in every direction by very long tortuous and wholly denuded vessels, which looked like the largest earth worms, and were of corresponding length. Most of the vessels came from the omentum, which had disappeared apparently by being incorporated with the tumor and by having its connective tissue and fat removed by absorption, leaving the blood-vessels bare. These vessels were either single or else grouped in large bundles, and had all to be ligated. By them the tumor had evidently been nourished, for what looked like a pedicle, was slender, long and twisted. It was lost in such a mass of livid veins that Dr. Goodell did not dare follow it up to its source. His diagnosis had been sarcoma of the omentum; but he was so uncertain of the character of the growth that he sent the specimen to Dr. Formad, who pronounced it a leukæmic spleen. It weighed not quite six pounds. The woman did did well for four days, then symptoms of embolism set in, the sputa became streaked with blood, and she died on the sixth day. So far as he can learn from the literature on the subject, his case made the eighteenth in which a leukæmic spleen had been extirpated, and all had died save one.

Dr. Harris said that the case of recovery after operation for removal of a leukæmic spleen, spoken of by Dr. Goodell, had occurred under Dr. Franzolini, of Modena, in North-eastern Italy. The proportion of leucocytes was small, which probably accounted for the recovery of the patient. The diagnosis had been made before the operation.

Dr. Parish had a few years ago seen a case with late Dr. Wallace, in which a diagnosis of the fibroid of the uterus had been made. A tumor the size of the two fists was found near the side of the uterus. The patient developed peritonitis and was tapped by the assistant physician; some dark fluid was withdrawn. Death took place a few months after, the peritonitis having been cured. At the autopsy, the spleen was found adherent to the uterus and to the pelvic brim.

Dr. Goodell called attention to the hæmoptysis and hæmatemesis in his case, which were the usual symptoms of a leukæmic spleen; but he had not been informed of them until after the operation had been performed, and, therefore, he did not have that clue towards forming a diagnosis.

Dr. Hamill exhibited

A Uterus Removed from a Woman in the last Month of Pregnancy,

and said: The opportunity to examine the uterus at an advanced period of pregnancy is not often afforded; and as this particular specimen presents several well-marked and interesting features, I felt that it would be of interest to place it before the society. The uterus was removed about twenty-four hours after death. I was present when the patient died and wished to remove the uterus immediately, but could not obtain the consent of the family. I shall very briefly call attention to the several conditions noticed: The outer surface of the uterus is studded in many places with syphilitic nodes. The woman had contracted syphilis early in her married life, and manifested other marked symptoms of the disease. There is also a small cyst of the broad ligament. The specimen presents quite markedly the contraction ring, or ring of Bandl. I give both designations advisedly, inasmuch as it is not definitely determined whether this ring represents the internal os, as Bandl asserts, or marks the boundary between the upper and lower uterine segment, as Schroeder believed. According to the investigations of MacDonald, Müller, Sänger and Lusk, this condition does not always exist. In three autopsies made by Lusk, he failed to find any trace of Bandl's ring. Schroeder, in a frozen specimen, found this ring very distinctly, but claimed that it was the dividing line between the upper and the lower uterine segment. Bandl holds the contraction ring of Schroeder to be the true internal os, and consequently one would expect to

find below this ring cervical mucous membrane, whereas the portion between Bandl and Müller's ring is covered by decidua. Bandl explains this by his three hypotheses: (1) the decidous membrane is crowded down into the cervix by the weight of the presenting part; (2) in primiparæ the advancing head strips off the mucous membrane, which is replaced by decidua; (3) the cervical mucous membrane is transformed into decidual membrane during pregnancy.

Another interesting feature, which the specimen demonstrates beautifully, is that condition pointed by Leopold and Lusk as seen in their Cæsarean sections, viz., the delicate filamentous bands running from the chorion to the decidua, which are the atrophied villi of the chorion. The attachment of the placenta is to the posterior wall of the uterus.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 16, 1888.

The President, A. Jacobi, in the chair.

Dr. Idele A. Seibert read a paper upon

Cholera Infantum and the Weather,

and gave as his excuse for doing so the fact that, while much had been said upon it, definite knowledge had not been arrived at.

Dr. Seibert had collected all the cases of acute gastro-intestinal catarrh in children under five years of age occurring at the German dispensary during the period of ten years, from 1878 to 1888, and had compared their frequency and severity during the several months and years with the meteorological phenomena during the corresponding dates. The total number of cases was 8036. Of these the largest number occurred during the warm weather months, June, July, August, September, October, and the fewest during the remainder of the year, the cold weather months, so that we might properly continue to call it a summer complaint. But its relation to heat, to moisture and to winds was not what many had been led to believe. His statements in this respect were founded on a study of several charts in which the figures given were thoroughly analyzed and compared. Besides a study of these eight thousand cases, he had also made a study of the number of deaths from the same disease during the same period of time, as shown by the statistics at the Board of Health. The following statements grew out of his investigations:

1. Hot weather, either dry or moist, is not necessary for an epidemic appearance of summer complaint.

2. Warm weather, either dry or moist, showing minimum daily temperatures of not less than 60° F., brings on the epidemic appearance of cholera infantum invariably in every year, irrespective of the height of the maximum degree of daily temperature, as in the latter part of June of nearly every year.

3. Summer complaint loses its epidemic character as soon as the minimum daily temperature falls below 60°, as in the latter half of October of nearly every year.

4. Therefore this disease cannot be brought about by the direct working of high temperature on the infantile body, but must have other causes.

As to what these other causes might be, Dr. Seibert was of opinion that it was chiefly spoiled milk. It had been shown by Dr. Edson and others that milk readily decomposed when of a temperature of 60° or above. That which was brought to the city was usually milked in the afternoon or evening, and transported to the city during the hottest hours of the day, and was jostled over the streets before reaching the consumer, being thus subjected to all the conditions favoring decomposition. His statistics also showed, contrary to general belief, that the mortality from summer complaint was less during August than during July. This difference might be accounted for in different ways, the chief one being probably that parents had their attention more fully aroused by that time to the necessity for proper precautions.

The paper was discussed by Drs. L. E. Holt, J. Lewis Smith, A. Caillé, A. M. Jacobus, and the President, most of whom expressed the opinion that cases classed as summer complaint were not all of one disease.

The President believed that cholera infantum proper was in a measure due to the action of heat, as most cases occurred during a hot spell; while ordinary cases of acute gastro-intestinal catarrh, which were the more frequent, existed during warm months, when the temperature could not be called hot.

Dr. J. Lewis Smith thought the cases occurring during the cold months had not the same origin as those developing during the warm months. Those who had given most thought to the cause of summer complaint, he said, were of the opinion that it is due to a micro-organism.

Reports of Clinics.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

MEDICAL CLINIC—PROF. OSLER.

Multiple Aneurism of the Aorta.

The post-mortem specimens from this case were brought before the class. The first sac took its origin from the upper part of the ascending portion of the aortic arch. The body of the tumor bulged forwards, pressing against and eroding the manubrium, the ends of the clavicle, the costal cartilages, and first and second ribs of the right side, and formed an external mass as large as a cocoa-nut. The skin had been eroded at two points, situated over the most prominent portion of the sac, and through these openings a slow but constant hemorrhage occurred. A second aneurism, filled with firm laminated clots, was found at the beginning of the descending portion of the arch, and a third was situated below the diaphragm, just above the origin of the cœliac axis. This also was filled with firmly organized clots.

Previous to his death, this man had complained only of some pain in the chest and moderate dyspnœa on lying down. Otherwise he was in excellent health. The cause of death was exhaustion consequent upon the uncontrollable hemorrhage carried on through the two erosions in the skin. Fatal hemorrhage from external openings such as these is of exceedingly rare occurrence. The heart was found to be very slightly enlarged; aneurism seldom produces any cardiac hypertrophy.

Pneumonia.

The patient was a man, 34 years of age. He had had a bad cough for a week previous to his admission. On the day before he presented himself here the cough grew much worse, dyspnœa became a prominent symptom, and increased pain in the right chest occasioned much distress. There were also heightened temperature, chilliness and vomiting. On admission, the temperature was 101°, respirations 36, pulse 82. The cough was frequent, and accompanied by a rusty sputum. Percussion on the right side gave a high pitched note in the lower axillary and infra-scapular spaces, but auscultation only a few indistinct râles, without definite blowing breathing. The temperature rose rapidly during the ensuing night, and by morning had reached 104°. Here it remained throughout the day, and then fell to the normal within the next thirty-six hours. The treatment consisted in nitric ether and citrate of potash, and dry cups over the affected area, followed by poultices.

Remarks.—The lecturer regarded this case as a striking instance of a class of pneumonias in which one might find all the rational symptoms of this disease with an utter absence, or scarcely appreciable presence of any of the physical signs. Three or four days may pass, during which cough, thoracic pain, rusty sputa, quickened respiration, and high temperature may possibly be well marked, before the local signs of exudation and solidification reveal themselves. It is to be remembered that the lung is an organ of considerable capacity; that it fills quite a large space; and, hence, if the inflammation happens to be deep-seated or central, it will take very careful auscultation to discover the customary râles. It is only when the pneumonia is superficial that the râles and blowing respiration are of easy recognition. As to the treatment of a mild, uncomplicated case such as this, it is, of course, very simple. Scarcely anything more is necessary than confinement to bed, and a mild aperient and diaphoretic course of remedies.

Pleurisy; Empyema; Phthisis.

This young woman, aged 28, was admitted to the hospital last March with all the signs of pneumonia of the right base. She was placed under treatment for that disease, and in a reasonable time the cough lessened, the sputa diminished, the respiration became less frequent, and the pneumonia seemed to have run its course; but, in spite of all this, the temperature remained high and dulness was still found at the base of the lung. In addition, the patient had several chills, and there occurred profuse sweating. It was then discovered that an empyema existed, and, a short time subsequently, the lung displayed unmistakable evidences of tuberculosis.

Now the question arose: "Was this principally a case of pleurisy, tubercular in its origin, or was it a case of what has been called acute pneumonic phthisis, with the pleuritic lesion secondary to it?" Many authorities now assert that the large majority of pleurisies are really of tuberculous origin, and that they are preliminary to, or are accompanied by, tubercular deposits in the lungs. Dr. Osler thought this was going too far. He grants that many cases of pleurisy have this for their exciting cause, no doubt; but he is not

yet ready to accept the doctrine that the majority of them are due to it.

Gastro-Intestinal Dyspepsia.

John S., aged 56, ship's steward, has suffered more or less constantly for several months from imperfect digestion. During the last three months an obstinate diarrhœa has added greatly to his discomfort, and it is for this disorder that he now applies for treatment. He averages about four stools in the twenty-four hours. There is no tenesmus, no blood, and no pain of any account. There is an entire absence of that tenderness over the large bowel which would indicate the existence of ulceration. Chronic dysentery is thus excluded. The patient has noticed that the diarrhœa is markedly influenced for the better by a restricted diet. A full meal, on the other hand, is followed by an aggravation of the diarrhœa and by a distressing degree of flatulence, the wind passing, as the patient says, "both ways." From these facts the case is diagnosed as one of gastro-intestinal dyspepsia, the mass of semi-digested food being responsible for the appearance and continuance of the diarrhœa.

Treatment.—The lecturer thought that certain of the artificial digestive ferments might be employed here with advantage. Preparations containing pepsin, pancreatin, etc., were clearly indicated and would, doubtless, prove of benefit. In addition to these, however, Dr. Osler spoke warmly of the value of naphthalin in doses of v to viij grains, taken in capsules immediately after meals. Should the diarrhœa persist, bismuth was to be used in preference to any other remedy, but it must be given in larger doses than those usually prescribed. Grains xv–xxx should be given three times daily in order to secure a favorable result.

—A new and ingenious test for detecting the addition of water to milk is reported, based upon the fact that all well and river water contains nitrates of either calcium, sodium, potassium, or ammonium in varying proportions. The presence of either of these, according to the source of the water, may easily be determined in the residue left upon evaporation of the water. These nitrates, in the proportion present in the drinking water, produce a blue color with diphenylamine sulphate. In testing, twenty drops of the diphenylamine sulphate is placed in a saucer and a little of the suspected milk poured into it. In the presence of only five per cent. of well water of ordinary quality in the milk, it will gradually assume a blue tinge.—*Quarterly Therapeutic Review*, January, 1888.

Periscope.

Case of Poisoning with Potassium Bichromate.

Dr. W. Norton Whitney, in a communication to the *Sei-I-Kwai Medical Journal*, of Tokyo, Japan, December, 1887, reports that a case of poisoning by potassium bichromate recently came under his notice, which he thinks worthy of reporting on account of the large amount of the substance ingested, and the fortunate recovery made through prompt use of antidotal measures. The patient was a young married woman, about two months pregnant, who through mistake took a swallow of a saturated solution of potassium bichromate, which had been used for charging a carbon battery, and also contained sulphate of mercury and sulphuric acid. The fluid had been carelessly placed in a Crosse and Blackwell fruit bottle, marked "Raspberries," and was supposed to be raspberry syrup. The amount of fluid ingested was estimated to contain about twenty-four grains of the bichromate and three grains of the sulphate of mercury. Immediately upon its ingestion it occurred to her, from the astringent taste of the fluid, that she had taken poison; and, recalling the fact that the white of an egg is a safe antidote for corrosive poisons, she immediately, and within five minutes after she had taken the fluid, swallowed the white of one egg. Nausea and vomiting of a bright yellowish substance immediately followed. The nausea and vomiting continued for some time. Dr. D. B. Simmons was called, and ordered some more white of egg, and some warm water and bicarbonate of soda, which were given about half an hour after the poison had been taken. At this time the nature of the fluid taken had not been discovered. Nausea and vomiting continued for about seven hours after, vomiting taking place about twenty times in that interval. Four hours later, castor oil was given, which acted in a few hours. Eight hours after ingestion of the poison, a slight hemorrhage from the genitals began, and continued for a short time, not amounting, however, to more than a drachm altogether. The patient had been sent to bed an hour after the taking of the poison, and she remained there for forty-eight hours. The fifth day after the accident she was carried in a hammock twenty-two miles, and on the sixth day rode by railway sixty miles to Tokyo. No ill effects have since been noticed, and the gestation had proceeded up to the time of the report three and one-

half months more. It is a matter of doubt in the author's mind as to whether the hemorrhage was due to the oxytocic nature of the poison, or to the violent and continued emesis; the fact, however, of there being so little hemorrhage and its early arrest, although a miscarriage at six weeks had taken place a year previous, points to the probability that it was entirely due to the vomiting.

Contractions of the Uterus during the Whole of Pregnancy.

Dr. J. Braxton Hicks, who is well known for his investigations upon the contractions of the uterus during pregnancy, has recently communicated two papers on the subject to the *Lancet*, January 14 and 21, 1888. The following is a brief *résumé* of these papers: 1. During the whole of pregnancy the uterus contracts at intervals, which vary much, but commonly last from five to twenty minutes, and it remains in contraction for a shorter time, say from three to five minutes. 2. If the examining hand is placed at the time of contraction on the uterus the latter will be firm, pear-shaped, and the fœtal parts not readily, if at all, detectable; if the hand is placed on it during the state of rest, or is allowed to remain on till the firm state is passing off, then the outline of the uterus is indistinctly felt; sometimes it cannot be felt at all, while the fœtus can be more or less clearly made out and can often be pressed with the fingers outside into various positions, even as early as the fifth month. 3. By noting these facts, we are enabled with ease, in general, to decide as to the existence of normal pregnancy, to diagnosticate between this and various tumors, both uterine and abdominal, between pregnancy and distended bladder, and other conditions easily called to mind by the practitioner. 4. That these intermittent contractions have the physiological use of emptying the loaded uterine veins, changing highly carbonized blood for that more aerated. 5. That from observations which he has made he is inclined to think that there is some pretty constant relationship between the accumulation of this highly carbonized blood and the fœtal movements, and also between the fœtal movements and the uterine contractions.

Restored to Sight after sixty years of Blindness.

In the *Lancet*, January 7, 1888, Dr. David McKeown reports the case of a fiddler, 63 years old, who had been blind, when first seen by Dr. McKeown in August, 1883, for sixty years. When one and a half years old, he lost the sight of both eyes from an attack of small-pox. The right eye lacked perception of light, but the perception of the left was good. There was a dense central opacity extending into the upper half of the left cornea, and the iris was adherent all around to the margin of the opacity. An iridectomy was performed, opposite the transparent cornea above, which was the only place available for such a purpose. A year after the operation, his condition was about as follows: the cornea opposite the artificial pupil was a little milky; the use of the eye was attended with some difficulty, on account of the position of the artificial pupil, which caused strain upon the inferior rectus; the presence or absence of the lens could not be determined; the result of a trial with glasses was practically *nil;* the vision which he had gained by the operation enabled him, when in the streets, to dispense with the stick, which, before the operation, was a necessity; he could count objects of a line and a half in diameter when about a line distant from each other; he recognized comparatively small differences in size. His color perception was good, and his color education progressed very rapidly.

The author regards this case as unique, considering the early age at which vision was lost, the prolonged period of blindness, and the gratifying result of the operation.

Differential Diagnosis of the Different Syphilitic Ulcers.

G. Wertheim states in the *Weiner med. Blätter*, 1887, No. 11, that he believes that he can, in every case, say with certainty whether he has to deal with a hard chancre or a soft, or so-called mixed chancre. His method of procedure consists in first treating the pus of the chancre with a solution of vesuvin (one thousandth of one per cent.); then with a solution of caustic soda, hydrochloric acid, chloride of sodium and distilled water. According as the resulting crystals form themselves into a granular structure, or into sheaves, or show a combination of granules and sheaves, the sore is one or the other of the three kinds of chancre. The author promises a successful result from the investigation only when his highly minute directions are followed in the most accurate manner; and the details of the method cannot be reproduced in an abstract.—*Centralblatt f. d. med. Wissensch.*, December 10, 1887.

Perichondritis of the Larynx.

At a meeting of one of the medical societies of Vienna, on December 5, 1887 (*Deutsche med. Wochenschrift*, January 26, 1887), Dr. Schnitzler exhibited a case of marked perichondritis of the larynx which had been cured. The patient was taken sick at the end of December, 1885, with cough and hoarseness, and was subsequently unsuccessfully treated by Prof. Schrötter for two months with local applications of iodine and glycerine, and nitrate of silver. He then came in July to the polyclinic complaining of severe horseness, cough, and difficulty in swallowing. There existed at this time a swelling of the whole mucous membrane of the larynx. The epiglottis was thickened, and on both sides of it were ulcers; the arytenoids were decidedly thickened, the vocal cords reddened and swollen, but the inter-arytenoid mucous membrane unchanged. The presence of ulcers upon the epiglottis, while the larynx remained intact, was in favor of syphilis, although tuberculosis was suggested. There was dulness at the apices of the lungs, but an examination for tubercle bacilli gave a negative result. The patient explained that he never had had syphilis, but that ten years before he had had gonorrhœa which was complicated with buboes, and that there never had been any secondary symptoms. Insufflations of iodoform, sprayings with solutions of corrosive sublimate, and inunctions had no effect; on the contrary, the swelling decidedly increased, so that the patient nearly suffocated. Recovery followed the use of iodide of potash from three to five times a day for six weeks.

Case of Cystic Goitre Treated by Enucleation.

In the *Bristol Medico-Chirurgical Journal*, December, 1887, Dr. C. T. Vachell reports a case of cystic goitre, which occurred in a woman 22 years old, who was admitted to the Cardiff Infirmary, October 19, 1886. She had first noticed the tumor about nine years ago, and since then it had slowly and painlessly increased in size. Latterly, it had somewhat interfered with breathing, there being occasionally a choking feeling. At the time of her admission the tumor was about as large as an orange, and occupied the front of the neck, inclining to the left side. It was painless, firm, and fairly movable, fluctuated distinctly, and rose and fell with the act of swallowing. One large artery was felt entering at its right upper margin. An exploring needle was introduced, and it was found to be a single cyst and to contain fluid of a reddish color. On October 27, chloroform was administered for the purpose of "shelling out" the cyst, but the patient became so pallid that it was not considered advisable to proceed; four ounces of a reddish fluid were, however, removed with the aspirator. By October 30, the cyst had refilled; and on November 3, the patient was etherized, an incision about two and one-half inches in length was made through the skin, over the most prominent part, and the cyst enucleated. Free hemorrhage occurred from two vessels, which were readily secured, and this done there was no further trouble in the operation. A drainage-tube was inserted and the wound dressed with carbolic gauze. The tumor weighed eleven and one-half ounces, and contained five and one-half ounces of fluid. It measured nine inches in circumference and was unilocular; the walls were from one-eighth to three-sixteenths of an inch thick. Some depression followed the operation, but the patient was discharged, cured on November 23, 1886.

Fatal Hemorrhage from the Tonsil.

Dr. J. N. Hall, of Sterling, Colorado, reports the following case in the *Boston Med. and Surg. Journal*, Dec. 22, 1887: Theodore W., about twenty-six years of age, a cowboy, was attacked with quinsy, about October 16, and bled severely from the mouth. He does not know the origin of the blood, which, he says, amounted to over a quart. He was about twenty miles from a physician at the time, and did not consult the writer until he had bled slightly at several other times. He wishes now (October 30) to know "what to take to get strong again."

At that time there had been no bleeding for several days, and the left tonsil, although somewhat swollen, was not very troublesome. He was given tincture of the chloride of iron, with fluid extract of ergot. After two days, feeling better, he went away from town to the ranch, forty-one miles distant. The next day but one, and during the absence of the writer, he returned, reporting three severe hemorrhages. He was very pale and weak. Dr. C. S. Stone found the origin of the blood to be in the right tonsil, in a cavity left by the evacuation of matter during the attack of quinsy. He applied styptics and no bleeding took place for ten hours. The patient was instructed to press upon the tonsil, in event of bleeding, with the finger. At 10 P.M., and at midnight, bleeding occurred, but was checked by the above plan before the

arrival of medical aid. With the assistance of Dr. Stone, subsulphate of iron was applied to the interior of the cavity. The patient in each hemorrhage lost, by Dr. Hall's estimate, about twenty ounces of blood. He was now pulseless at the wrist, extremities cold, and the heart's action very feeble: 150 per minute. The left tonsil was now greatly swollen, and a little matter was evacuated with a broad exploring needle. Two days later a decomposing clot, nearly as large as a hen's egg, was coughed from the throat, and the tonsil returned to nearly its natural size. For eleven days the patient improved, and was considered out of danger, having been on the street daily for a week. Dr. Hall then continues: "I was called suddenly at 2 P.M., October (November?) 16, to go a distance of one hundred and sixty-five feet to see a very sick man. The time occupied in going was extremely short, but it proved to be this patient lying on the floor moribund. No blood had been lost on the street, but, during the time the writer walked the distance named, the patient had lost blood so rapidly by the mouth and nostrils as to be so far gone that no measures of relief were taken, because they were considered utterly useless. As the writer entered, a stream of blood, as large as could flow, came from the mouth and nostrils, but it stopped shortly. The pulse was perceptible for a few seconds only after arrival.

"No post mortem was obtained. It would seem impossible for death to occur so suddenly from a hemorrhage from any vessel less than the internal carotid. It was learned after death that the patient had stated a short time before that he felt 'something swelling ing his throat.'

"Probably the ulceration weakened the wall of the carotid artery, and the bleeding came from an aneurismal dilatation of the vessel at that point. Such rare cases have been previously reported."

Corrosive Sublimate in the Treatment of Diphtheria.

J. Stumpf reports to the *Münchener med. Wochenschr.*, No. 12, 1887, that after having passed through an epidemic of diphtheria from May, 1883, to March, 1884, with a mortality of 76 per cent. of the cases, he treated in December, 1884, a boy two and a half years old, who was suffering with diphtheria. He prescribed for this boy inhalations of corrosive sublimate every three hours. These were given by means of a Richardson atomizer, the strength of the solution being one to one thousand. After a few days the boy was restored. Since that time he has treated thirty-one cases of diphtheria exclusively with inhalations of corrosive sublimate, and under this treatment he has lost only one eight-year-old boy in whom, however, the inhalations could be employed only twice. Another nine-year-old boy died four weeks after the beginning of the disease from a sequela. The other twenty-nine cases recovered quickly and completely. Under the employment of these inhalations, in from twenty-four to forty-eight hours the temperature fell from 104° or 105¾° to normal, without the employment of any other antipyretic. Simultaneously with this fall in temperature, there could be demonstrated a marked cessation in the formation of the diphtheritic membrane, which became defined against the healthy mucous membrane of the throat by a clear line of demarcation; the difficulty in swallowing also diminished; the patients desired food and drink, while the membrane, after remaining adherent for from three to five days longer, was then gradually cast off. No symptoms of intoxication whatsoever were observed under this plan of treatment. The only symptom of the action of the mercury was salivation, which was present in every case, but ceased within three or four days after the withdrawal of the remedy.

With reference to the quantity of corrosive sublimate which is thus employed, the author makes the following calculation: One drachm of the solution is necessary for each inhalation; therefore, six ounces suffice for fifty atomizations. Fifty atomizations of a solution, one part in two thousand, will be the maximum allowable dose. But fifty inhalations are scarcely necessary, and besides, more than half of the fluid is rejected by the child. The author employs simply a watery solution of a strength of one part in one thousand for children over six years of age; and for children between two and six years of age, one part in two thousand; while for children under two years of age, one part in three to four thousand.—*Centralblatt f.d. med. Wissensch.*, Dec. 10, 1887.

—A whole family at Versailles, consisting of the parents and two children, was poisoned with conium, which had been used instead of parsley in a dish of vegetables. The patients, being dangerously sick, were taken to the hospital for treatment and recovered. A variety of conium, much resembling parsley, is said to grow in all the backyards and gardens in Versailles.—*Western Druggist*, Jan., 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

ENLARGED SUPRACLAVICULAR GLANDS IN CANCER OF THE STOMACH OR UTERUS.

In October, 1886, M. TROISIER called the attention of the Société des Hôpitaux of Paris to the occurrence of enlargement of lymphatic glands in the supraclavicular region, and especially above the left clavicle, in a certain number of persons with cancer of the stomach. A similar observation was reported by Millard within a week after this; and in the month of November Raymond published an account of a case of cancer of the neck of the uterus in which there was an enlarged lymphatic gland in the left supraclavicular region.

Enlargement of the glands in this situation, in persons with cancer of the stomach or uterus, is not of so frequent occurrence as to have attracted very much attention to the subject; but it is easy to see that, when it does occur, it might be a very important diagnostic sign. For there are not a few cases of disease of the stomach, when the existence of cancer is suspected, in which it would be of great value to have some tangible evidence to confirm the probable diagnosis. The same thing may be said, with less force, it is true, of cases of cancer of the uterus; because it sometimes happens that cancer is suspected under circumstances which make a thorough examination by the vagina impracticable or undesirable.

In the *Gazette Hebdomadaire de Méd. et de Chir.*, Jan. 20, 1888, PETIT reports the case of a woman, seen in 1887, with epithelioma of the cervix uteri, and with a gland enlarged to the size of a pigeon's egg above the left clavicle, which had the characteristics of hard cancer. In the same journal there is a report of a commission composed of MM. Bucquoy, Raymond and Troisier, upon this interesting subject. From the report it appears that Troisier has observed enlargement of the lymphatic glands above the clavicle, attaining the size of a hen's egg, in another case of cancer of the uterus, and he reports a similar case observed by Hutinel as long ago as 1881. Troisier has seen the same thing in a case of cancer of the left ovary.

The observations so far recorded indicate that enlargement of the supraclavicular glands, in cases of cancer within the abdomen or pelvis, is usually associated with similar enlargement of the glands in other superficial situations. But it sometimes occurs by itself. It also usually appears long enough after the implication of the internal organ to make it of less value as an aid to diagnosticating the nature of the internal disease than as an evidence of generalization of the disease, and as an indication that a surgical operation cannot be expected to eradicate it. Nevertheless, as we have stated, it does occur independently, and it also sometimes occurs early; so that in a certain number of cases it may be of great service in establishing a diagnosis which would otherwise be uncertain.

The explanation of this phenomenon, which is offered by Troisier, is that cancer elements are carried by the thoracic duct to the orifices of the ducts of the cervical lymphatics, and thence, by a *reflux*, to these glands. This explanation appears to us entirely unsatisfactory, and we cannot find any which

is less so. But, even if the explanation of the occurrence is not what we might wish, the occurrence itself is of sufficient importance to warrant calling the attention of our readers to it. For the region concerned is one so accessible to investigation that surgeons may well include it in any examination they may have an opportunity to make; and it may be that, if attention be directed systematically to the matter, it may be found that enlargement of the supraclavicular glands occurs oftener than has been heretofore supposed in cases of cancer of the abdominal or pelvic viscera, and that this enlargement may be a very valuable aid to its diagnostication.

THE TREATMENT OF DIPHTHERIA.

In the *Deutsche med. Wochenschrift*, February 2, 1888, Dr. v. Kaczorowski, of Posen, publishes an abstract of a paper on the subject of the treatment of diphtheria, in which he expresses views which we believe to be thoroughly sound. He discusses the nature of this disease, and outlines his own method of treating it. This consists in administering mild purgatives, preferably castor oil, and half tablespoonful doses of a mixture containing two parts of tincture of iodine and five parts of common salt in five hundred parts of water. This dose is to be slowly swallowed every quarter of an hour. He attaches great importance to the effect upon the throat of mild purgatives given every day while the disease is active, and to the local influence of a mild disinfectant solution such as is described above. Chlorate of potash, he believes to be an unsafe remedy; and prefers the combination of tincture of iodine and chloride of sodium, because it is safe, easy to take, and does not interfere with the appetite. It can be used also for washing out the nasal passages when these are implicated. In grave adynamic cases or when the membrane is putrid, he administers camphor and benzoic acid, and alcoholic stimulants, and pays especial attention to the nutrition of the patient, and to securing an abundance of fresh air, even in cold weather.

In regard to medication, Kaczorowski expresses a great horror of mercurials, and especially of corrosive sublimate. His objection to this class of remedies is purely theoretical, however, and we believe it would disappear if he used them scientifically. We think that the purely empiric administration of large doses of calomel at the outset of diphtheria is often of great service. This may be partly due to the fact that it usually produces free catharsis; but it certainly seems to do good even when no catharsis follows its use.

In the main, we think the views of Kaczorowski are correct, and we would especially endorse his deprecation of violent applications to the throat. We believe that there is little occasion for making them, especially in the case of children, who are often needlessly tortured in this way. Much more can be accomplished with teaspoonful doses of lime water, swallowed slowly every hour, than those who rely upon sprays and gargles, and local applications of various salts of iron or of strong acids, or of powerful disinfectants would believe. Keeping the bowels open, we believe to be one of the most important parts of a judicious treatment of diphtheria; and for this purpose we think no drug is better or so easy to administer as calomel in small and frequently repeated doses—for children, one-tenth of a grain, with a grain or two of sugar, given every hour until a stool is passed.

Tonics are rarely needed, but when they are called for, we believe the best to be small doses of whiskey—a teaspoonful every hour or two, for an adult, and correspondingly smaller doses for children—with perhaps a grain or two of quinine three times a day, and a few drops of the tincture of the chloride of iron in glycerine.

These measures, with good hygiene and good diet, will rarely fail to secure a satisfactory result in cases of ordinary severity. It may be pure luck which leads a man like Kaczorowski to think that they can be relied on, as a rule, in the treatment of diphtheria, and he may have had only simple and light cases to treat. But, again, he may not hav

spoiled his cases with too great zeal in treatment, and some of them may have been easy to treat because he did not make them hard.

THE TREATMENT OF TYPHOID FEVER.

In the *Archives Générales de Médecine*, January, 1888, M. Albert Robin has a paper on the treatment of typhoid fever, and the typhoid state in general, which is deserving of the most careful consideration He opposes the current theories in regard to the causes and the significance of high temperature, and the present practice in endeavoring to suppress it. He believes that chemical and physiological investigation does not support the view that high temperature is due exclusively to increased combustion in the body, or to diminished elimination of caloric. For this reason he is opposed to methods which seek simply to restrain the production of heat, or to abstract it rapidly; and he thinks it unwise to give heroic doses of so-called antipyretics, or to push cold baths or cold packing until the temperature falls decidedly. On the other hand, he shows, by a process of reasoning which is so admirable that we regret being unable to reproduce it in full, that more is to be expected from careful regulation of diet, copious supplies of drinking water, abundance of fresh and cool air, and medicines which are antiseptic and promotive of oxidization in the tissues, than from any attempt to combat the temperature alone.

He speaks particularly of the undesirability of trusting to massive doses of quinine, antipyrine, alcohol, and so forth; and inclines to the use of simple eliminants and moderate washings combined with the hygienic measures alluded to above.

In this we wholly agree with him, feeling sure that typhoid fever can be treated satisfactorily without the use of large doses, and especially of large doses of quinine and alcohol. The latter we believe to be absolutely dangerous, and to be only excused, but never justified, by the desperation in which one is apt to fall who sees a patient getting worse instead of recovering, and who thinks that, if a little of a remedy is good, more of it must be better.

Our own conviction is strong, as we have indicated already in an editorial in the Reporter, December 3, 1887, that the time when a case seems desperate is the very time when the physician should most courageously restrain the natural disposition to fly to desperate remedies. If the patient should die—well, some must die, or man would be immortal! But, he may yet get well; and, we believe the likelihood of this happy issue of the case is materially improved by sticking to gentle measures, and sparing the patient from having to struggle with the influence of violent medicament, as well as with the depressing forces of his disease.

QUACK ADVERTISEMENTS IN RELIGIOUS NEWSPAPERS.

Since the publication of our editorial in the Reporter for Dec. 31, 1887, on quack advertisements in religious newspapers, we have received a number of letters expressing concurrence with our opinions and sympathy with our endeavor to so direct attention to the subject as to lead to some improvement in the moral tone of these religious guides. Some of these letters come from the editors or publishers of religious papers, and—as might have been expected—from those who do not sin in the way under discussion. Some of these letters bear witness to the hardships which go hand-in-hand with a strict adherence to principle, and to the sense of injustice excited by seeing so-called religious papers, which are blessed with comfortable consciences, waxing fat, while the truthful and honest paper has some trouble in getting along. It is true that the *mens conscia recti* is a good thing to have; but, since the days of Ecclesiastes, those who try to do what is right would like to believe that the sinner was less comfortable without it than he appears to be. But the so-called religious papers which make money out of quack advertisements manifest a bluntness of moral sensibility, which leads some of our correspondents to doubt that anything will arouse them to a sense of their turpitude. We shall see, how-

ever. Our religious contemporaries will not forget that a similar state of affairs led Jonah to think it hardly worth while to go to Nineveh; and it may be that the so-called religious newspapers are not sunk as deep in iniquity, as some of the really religious newspapers seem to think.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

A MANUAL OF MEDICAL JURISPRUDENCE, WITH SPECIAL REFERENCE TO DISEASES AND INJURIES OF THE NERVOUS SYSTEM. By Allan McLane Hamilton, M.D., one of the Consulting Physicians to the Insane Asylum of New York City, etc. With illustrations. 8vo, pp. 390. New York: E. B. Treat, 1887. Price, $2.75.

This book is presented as an elementary treatise and book of reference for lawyers and doctors. None the less, it is much more than the author in his modest preface declares it to be. He discusses in considerable detail, and to an extent indicated by the number of pages the book comprises: Insanity, Hysteroid Conditions and Feigned Diseases, Epilepsy, Alcoholism, Suicide, and Cranial and Spinal Injuries.

The author's established position as a writer on diseases of the nervous system fits him peculiarly for preparing a book on this subject, and those who consult this one will not be disappointed. It is a book which might be studied with profit, not only by practicing physicians, but also by lawyers, to whom problems of medical jurisprudence are presented many more times than they ever are to courts of law. We believe that this subject is one which ought to form part of the education of every doctor and every lawyer, and that no one of these two classes should leave the study of it until the exigencies of a civil or criminal action make it imperative. As our readers are chiefly physicians, we would urge upon them the importance of knowing something about medical jurisprudence, and can recommend Dr. Hamilton's book as both instructive and interesting.

ELEMENTARY MICROSCOPICAL TECHNOLOGY. In three parts. Part I. The Technical History of a Slide, etc. By Frank L. James, Ph.D., M.D., etc. 8vo, pp. 107. St. Louis: St. Louis Medical and Surgical Journal Company, 1887. Price, paper, 50 cents; cloth, $1.00.

The author of this book has been led to prepare it because in his experience, as a student and as a teacher, he had not found any work in which the technical details of microscopical work were not so scattered throughout the departments devoted to micrography as to make them to a certain extent useless to beginners. In order to supply the want which he felt, he has prepared a book in which nothing but technical detail is considered, and which we can heartily commend to beginners in microscopy. This part of his work deals simply with the steps required to prepare a specimen mounted permanently upon a slide, and omits no necessary detail of this procedure. The author's style is clear, and his instructions are entirely trustworthy; and we think that his book is calculated to be of very great service to the class of persons to which it is addressed.

SPINAL CURVATURE, COMPRISING A DESCRIPTION OF THE VARIOUS TYPES OF CURVATURE OF THE SPINE, WITH THE MECHANICAL APPLIANCES BEST SUITED FOR THEIR TREATMENT. By R. Heather Bigg, Assoc. Inst. C.E., etc. Illustrated by the author with numerous pen and ink drawings. 8vo, pp. 128. London: J. & A. Churchill, 1882. Price, $1.00.

This book is not new, but it comes newly to our table. It contains plain and practical instructions as to the nature and proper treatment of the different varieties of curvature of the spine, both those dependent upon alterations in the bones and those due to nervous and muscular defects. It is marked by evidence of good common sense, and we believe is a safe guide in the matter of which it treats. It will interest Americans to know that Mr. Bigg strongly opposes the view that the plaster-of-Paris jacket of Sayre is a panacea for spinal curvatures, and that he goes so far as to assert that, when it is the best appliance for any given case it need not be applied with the aid of suspension. These opinions are not so singular now as they were when Mr. Bigg first made them public; but it is interesting to note the plainness with which he states them, and the fairness with which he maintains them.

Pamphlet Notices.

I. An Address from a Special Committee of the College of Physicians of Philadelphia to the Medical Societies of the United States, Concerning the Dangers to which the Country is Exposed by the Ineffectual Methods of Quarantine at its Ports, and in Regard to the Necessity of National Control of Maritime Quarantine.

II. Report of the Committee of the College of Physicians of Philadelphia, Appointed to Investigate the Efficiency of our Quarantine Arrangements for the Exclusion of Cholera and other Epidemic Diseases. *Printed for the College*, 1888. 45 pp.

The Galvano-Cautery Sound and its Application, Especially in Hypertrophy of the Prostate, with Reports of Cases, by Robert Newman, M.D., of New York. From the *New England Medical Monthly*. 53 pp.

The Structure of White Thrombi. By W. H. Welch, M.D., Baltimore, Md. From the *Transactions of the Pathological Society of Philadelphia*, vol. xiii, 1887. 22 pp.

—We have already, in the Reporter, Dec. 24, 1887, published the address of the College of Physicians of Philadelphia to the Medical Societies of the United States, and need not further commend it to our readers. The second part of the pamphlet before us, although it antedated the first, furnishes an interesting and instructive appendix to this, and deserves to be carefully studied in connection with it.

—Dr. Newman's paper, which he read at the Ninth International Medical Congress, contains a strong argument for the use of a galvano-cautery which he has devised in the treatment of enlargement of the prostate gland, supported by accounts of

eight cases in which he has used it, introduced through the urethra or after a supra-pubic cystotomy. The reason for Dr. Newman's enthusiastic faith in this method is that, in his experience, "it has benefitted or cured all cases under observation; a reasonable time has passed without any relapse; it has caused no pain, no detention from business or pleasure; no untoward after symptoms or circumstances have ever occurred."

—Dr. Welch's paper contains an admirable summary of the literature of the subject of white thrombi, together with critical remarks upon it, and an expression of his own views in regard to their structure and mode of formation. These views are founded in part upon the results obtained by other observers and experimenters, and in part on his own observation and experiments. He assigns a very important part, in the formation of white thrombi, to the "hæmatoblasts" of Hayem, called also "blood-plates" by Bizzozero, and "blood-plaques" by Kemp and by Osler. The discussion of this subject is too recondite to permit a satisfactory brief analysis of it, and we must refer our readers to Dr. Welch's paper for information as to the present state of knowledge in regard to it.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—Lea Brothers & Co., Philadelphia, announce the preparation of a *Clinical Atlas of Venereal and Skin Diseases*, by Robert W. Taylor, A.M., M.D. It is to be published in eight imperial folio parts, with 58 full-page chromo-lithographic plates, containing 191 figures. Price, per part, $2.50, to be sold only by subscription.

Correspondence.

Quack Advertisements in Religious Newspapers.

[We publish some of the letters received from our contemporaries in response to the Editorial of December 31, 1887, on this subject, selecting the first that came in chronological order.]

The Churchman (Protestant Episcopal.)
New York, Jan. 16, 1888.

Editor Med. and Surg. Reporter:

Sir:—The enclosed clipping is sent to us from one of our subscribers. Will you kindly inform us if it refers in any way to the *Churchman?* And oblige,

Yours truly, M. H. Mallory & Co.

[To this we replied: "The part of the editorial quoted which refers to the *Churchman* is that which contains the statement, "There are a few happy illustrations of the fact that, even in a religious newspaper, 'honesty is the best policy.'"

The Church at Home and Abroad. (Presbyterian.)
Philadelphia, Feb. 4, 1888.

Editor Med. and Surg. Reporter:

Sir:—I fully sympathize with the views you express about quack advertisements; but as our magazine does not advertise at all, it is probable that our contemporaries would not much heed what we might say.

Yours truly,
H. A. Nelson, Editor.

The Christian Register (Unitarian).
Boston, Feb. 4, 1888.

Editor Med. and Surg. Reporter:

Sir:—We shall be glad to print your article on quack advertising in religious newspapers. The *Register* has not published any such advertisements for years. It has lost thousands of dollars by pursuing this course. Still, we believe with you that our duty to the public requires it.

Yours truly,
Samuel J. Barrows, Editor.

The Church Record (Protestant Episcopal).
Southport, Conn., Feb. 4, 1888.

Editor Med. and Surg. Reporter:

Sir:—When the *Church Record* was started, about three years ago, it placed at the head of its columns and on all advertising circulars and slips, "No Patent Medicine Ads. Received." * * * We knew that there were remedies patented which were good and useful, but we were not qualified to judge between them, and even the best are not desirable for indiscriminate use. Therefore, we were fixed in our position. We believe we are the only general religious paper in the land which from start to the present time has maintained this position. We have done it at great financial loss and in the face of personal abuse, but we shall do it to the end.

Whether we agree with your editorial or not, you can judge from this. And we hold that publication of medical ads. is not a matter of taste or business management, but a direct iniquity. You may use this letter as you think best.

Yours truly,
C. G. Adams, Editor.

The Moravian.
Bethlehem, Pa., Feb. 4, 1888.

Editor Med. and Surg. Reporter:

Sir:—I beg to state that for upwards of a year *The Moravian* has declined to insert any advertisements of proprietary or quack

medicines, at considerable financial loss, but to the very great satisfaction of

Yours truly, EDWIN G. KLOSÈ,
Editor and Publisher.
Freethinkers' Magazine.
Buffalo, N. Y., Feb. 4, 1888.

EDITOR MED. AND SURG. REPORTER:

Sir:—I beg to differ with you. I consider that religious journals are precisely the ones that should publish these advertisements. That is the proper place for them. Religion is nothing but quackery. The class of papers that they should be kept out of is the scientific and free-thought papers, that advocate what is known to be true. There should be nothing but quack advertisements in the religious newspapers.

Yours truly, H. L. GREEN,
Editor and Publisher.

Some new Uses for Antipyrin.

EDITOR MED. AND SURG. REPORTER:

Sir:—Deeming any new use for an old drug equal in value to the discovery of another drug, I offer my conclusions as to the uses of antipyrin. As to its well-known efficiency and safety as an antipyretic in typhoid fever and pneumonia, I cannot speak too highly. Perhaps its uniformly pleasing effect in my hands has been due to the fact that I never give larger doses than 10 grains, repeating this dose in one or two hours, if necessary.

In an epidemic of typhoid fever in Imlaystown, N. J., I have used it with uniformly good results in twenty-one cases, in which the temperature rose above 103°. Most of the parties to whom I give antipyrin speak of the relief it has given them, which is good evidence of its beneficial action. I find many cases of dysmenorrhœa which can be relieved in thirty minutes with doses of 3 to 5 grains of antipyrin, repeated as may be required by recurrence of the pain. I will cite only one case in point: E. N., 32 years old, married, no children, has for twelve years been compelled to keep her bed or a lounge for two days at every menstrual period. She is now able to be around all the time, and suffer no pain, by taking 4 grains of antipyrin whenever she feels the pains coming on. Previously, the only relief was obtained from opium and belladonna suppositories, which did not relieve the nausea and vomiting accompanying the pain as the antipyrin does; and, besides, caused the patient to keep quiet another day after the pain had ceased, in order to recover from the effects of the opium.

I have also found the drug useful in cases of trigeminal neuralgia, of which I have notes of two typical cases. In the first case, a man 50 years old, suffered with neuralgia of the first division of the fifth nerve, and was for a while benefitted by quinine and opium, as usually administered. Finally this lost all effect, except that it still produced ringing in the ears. Subsequently, potassium iodide in drachm doses at bedtime seemed useful for a while; but it did not agree well with the stomach. At last I tried antipyrin, and have been able to relieve the neuralgia every time it has recurred since (for six months), with five grain doses given every six hours until he is relieved.

Another very obstinate case of neuralgia of the first branch of fifth nerve occurring in a woman 70 years old, who has been a great sufferer all her life, I find invariably relieved by four grain doses of antipyrin every six hours, until sleep occurs, which is the signal of recovery. She is often unable to sleep for five or six days and nights from the terrible agony, which opiates seem nearly powerless to relieve owing to the length of time she has used them. This patient, having tried so many "specifics," had no faith in any new drug; but, since trying antipyrin, is very careful not to get out of "headache powders." H. G. NORTON, M.D.

Imlaystown, N. J.

Chewing and Swallowing Glass.

EDITOR MED. AND SURG. REPORTER:

Sir:—Several months ago a negro-man, named Bill Jones (and I have no doubt it is the same man to whom Dr. Gracy alludes: REPORTER, January 14, 1888, pp. 61 and 62), registered with Kohl and Middleton of this city, the well-known Dime Museum proprietors, they advertising him as "The Greatest Phenomenal Glass-Eater of the Age." He bore the impress of perfect health, and acknowledged frankly, and, I believe, conscientiously, that he had at no time suffered from indigestion or any form of gastric disturbance. I may venture to say, without any degree of hyperbole, that one-half of the people of Chicago saw Jones perform the novel feat of chewing and swallowing glass, the majority of them believing, as may naturally be expected, that it was a sleight-of-hand performance. He disposed of a portion of a lamp chimney every hour for the benefit of the spectators, as it is a rule, I understand, for the Museum to change its audience every hour. Jones was billed for a three weeks' engagement at this Museum, during which

time he ate, according to Mr. Kohl's statement, on an average of two lamp chimneys a day, which would make a total, with the three Sundays included, of forty-two. His novel feat having become more generally known through its dissemination at large by the thousands of spectators that witnessed the performance, as well as extensive advertising, some physician suggested the practicability of calling on Mr. Kohl and asking his permission to exhibit Jones before a body of scientific, medical men to see whether or not it was a purely sleight-of-hand performance, or a typical case of glass-eating. Permission was granted, and Jones was subsequently taken to the Rush Medical College and there exhibited before a class of five hundred students, as well as several professors. Jones devoured with seemingly great gusto every particle of a lamp chimney which was brought into the lecture-room, the physicians in attendance watching every movement he made to see that it was not a pseudo-stomachic feat. A second one was ordered, which he ate with as much relish as the first. After disposing of the second, some one suggested another kind of glass, which was much thicker and of a blue color. Jones objected on account of the thickness of the glass, its color, and bitter taste, claiming that his stomach was peculiarly sensitive and would rebel against any kind of glass other than lamp chimneys, which he characterized as being "very sweet." After devouring the second lamp chimney, a probang was introduced and he vomited particles of the glass, which were slightly streaked with blood. The probang, however, was introduced more as a means to prove that the man *actually swallowed* the glass than for its well-known practical purpose of removing foreign bodies from the throat. One of the students procured another (a third) chimney, and urged Jones to dispose of that, to which he replied, "I do not like to overload my stomach now, as I have to eat one or two chimneys at the Museum to-night for the benefit of the spectators." *He actually eats the glass and discharges it from the bowels in the same state as when swallowed.* I have seen two other public performers eat glass, but not in such large quantities. Every one present regarded it as a *bona fide* case.

William Whitford, M.D.
146 Warren Avenue, Chicago.
Feb 7, 1888.

Correction.

The first prescription in Dr. Bundy's letter (Reporter, Feb. 11, 1888, p. 185,) should have contained: Dilute phosphoric acid, 8 fluid oz.; compound fl. extract of cinchona, 2 fluid oz. The prescription as a whole would then read:

Take: Sulphate of strychnine.....4 grs
Dilute phosphoric acid.....8 fluid oz
Comp. fluid ext. cinchona.....2 " oz
Madeira wine.....1 pint
Simple syrup.....6 fluid oz

Yours truly,
A. D. Bundy.

St. Ansgar, Iowa.
Feb. 14, 1888.

Notes and Comments.

The Scarlet Fever Germ.

The *St. James' Gazette* (London) has recently published an interesting account of the experiments of Dr. Klein and Mr. W. H. Power, of the Medical Department of the Local Government Board, in regard to the relation between a disease found on the udders of some cows at Hendon and scarlatina. The cow disease was not itself scarlatina, but by cultivation of the organisms obtained from cows the specific micrococcus of scarlatina was produced. Moreover, this cultivation was made in milk, and it was the milk of the affected cow that caused the scarlatina epidemic which gave rise to the inquiry. Then it was proved that the virus of the cow disease, if conveyed into the human body by the medium of milk, developed there into the germ of scarlatina; although between the cow disease itself and scarlatina there is almost every possible difference. This discovery suggested to Dr. Klein a further question. He had shown that the cow disease could set up scarlatina in the human subject; he would now find out whether the scarlatina germ was capable of producing the cow disease.

From a number of patients in the Fulham Fever Hospital Dr. Klein took minute quantities of blood. These were placed in tiny tubes, and transferred to the surface of nutritive gelatine. In the result he obtained clear evidence that in some of his experiments the blood contained organisms. In other cases no positive results whatever were obtained. But in four cases out of nine the specific organism was detected; and the organism so recovered from the blood of scarlatina patients was found to be exactly the same as has been cultivated from the virus taken from the teats of the Hendon cows. Dr. Klein does not hesitate to name this organism the micrococcus scarlatinæ, as having

a special character and a definite mode of existence. The next question was whether, itself capable of being cultivated from the cow disease, it was capable of being transformed back into the virus of that disease.

With a subculture of micrococcus scarlatinæ derived from scarlet fever in a human being Dr. Klein inoculated two calves. The first was killed after ten days, and from blood taken from it a growth was derived identical with the micrococcus scarlatinæ. The second calf was killed after twenty days, with the same results. In both animals an identical disease had been produced. Subsequently two calves were fed with milk mixed with the growth from several tubes of the same date and the same source as used for the other calves; and again the identical disease was produced; this disease bearing a great resemblance to that observed in the Hendon cows, except that there was no affection of the skin. But three out of four other calves —two of which were inoculated and two fed—were differently affected. Sore patches appeared and the skin became scurfy; and on each nostril of one of them there was a patch of eruption which decided the matter. From these skin eruptions were obtained "beautiful chains of cocci" coinciding with those developed from the virus of the cows. The circle was thus complete. A cow disease which is not scarlatina, nor anything like scarlatina, causes the animal to have sore teats. The exudations find their way into the milk-pail, and there develop into something which infects human beings with scarlatina. From the scarlet fever patient a few drops of blood are taken, and after the disease germ has been cultivated, it is passed into the system of a calf, which forthwith becomes attacked by the identical disease observed in the original cow.

But this is not all. A case of suspected condensed milk was brought under Dr. Klein's notice. Scarlatina had broken out, and could be traced to no other source. Sure enough, the micrococcus scarlatinæ was found in the milk, and experiments with it on animals yielded exactly the same results as before. Again, last January, a monkey died at Wimbledon of scarlatina contracted by drinking the milk of cows among which there prevailed a disease similar to that at the Hendon farm. Microscopic examination of the internal organs of the monkey revealed the same changes as occur in these organs in human scarlatina, and in the blood the scarlatina micrococcus was found. By means of this micrococcus the Hendon disease was again induced in animals. Dr. Klein may therefore claim to have discovered a hitherto unsuspected cause of scarlatina, in the form of a little noticed and less understood cow disease, quite distinct from the dreaded malady which—after certain developments of its germ—it produces in man.

Material for Pessaries.

Dr. Ernest Fränkel, of Breslau, in the *Illustrirte Monatsschrift der Aerztl. Polytechnik*, Jan., 1888, speaks of the great value, in the treatment of retroflexion of the uterus, of Thomas's pessary. He describes the drawbacks of hard rubber as a material for their construction, and a plan which was carried out for him by Härtel, of Breslau, of making them of glass. The only objection to this material is that it is heavy, and Fränkel suggests that the pessaries might be made hollow, so as to be lighter, without impairing their strength.

He also strongly commends the use of pessaries made of copper-wire, covered with celluloid, as being less liable to incrustration, less liable to change shape when exposed for a long time to the temperature of the body, and demanding less skill to adapt their shape to the requirements of individual cases.

The Sense and Senses of Animals.

Sir John Lubbock recently devoted a lecture to this subject in Green Street Hall, Edinburgh, and pointed out that the dog was generally admitted to be a loyal, true and affectionate friend of man; but, when the nature of the animal was considered our knowledge, he said, was very limited. This arose from the fact that attempts were made to teach animals rather than to learn from them. It had occurred to him that some such method as that which was followed in the case of deaf mutes might prove instructive if adapted to the case of dogs. He had tried, with a black poodle belonging to himself, and had made the following experiments: "He had taken two pieces of card, one blank and the other with the word 'food' upon it. He had put the latter on a saucer containing some bread and milk, and the blank card he put on an empty saucer. The dog was not allowed to eat until he brought the proper card to him. This experiment was repeated over and over again, and in about ten days the dog began to distinguish the card with the letters on it from the plain card. It took a longer time to make the dog realize the difference between different words. In order to try to discover whether

the dog could distinguish colors, he prepared six cards, marking two of them blue, two yellow and two orange. He put one of each on the floor, and tried to get the dog to bring to him a card with the same color as one which he showed the dog in his hand. After trying this for three months, he found that his experiment in this direction was a failure." Sir John Lubbock proceeded to state that he considered it doubtful whether ants could hear or not, but that it was possible that both they and bees might hear sounds so shrill as to make no impression on the human organ of hearing; and so perhaps with colors. The world might, to insects, be full of music which we could not hear, colors which we could not see, and sensations which we could not feel.—*Lancet*, Dec. 31, 1887.

A Cunning Malignerer.

L. M. Logan, who was arrested two months ago at Alton, Ill., on the charge of swindling, has meanwhile been swindling some eminent physicians out there. He was taken with a remarkable illness, which was finally diagnosticated as a tumor, or abscess, of the brain. To the mortification and disgust of the surgeons, he gave up shamming recently, and explained with frankness how he had dilated his eyes with belladonna, brought on vomiting by swallowing tobacco-juice, increased his pulse by striking his elbow against the wall, and brought on palpitation of the heart and blood-rushes to his face by forcing air into his lungs while he contracted his chest. He also had frequent but bogus fits, but will now catch genuine ones from the jail authorities.—Philadelphia *Ledger*, Jan. 24, 1888.

Treatment of Pistol-shot Wounds.

Dr. Paul Reclus, surgeon at the Hôtel-Dieu, Paris, in a recent volume (*Cliniques chirurgicales de l'Hôtel-Dieu*), expresses himself strongly against exploring for a ball after a wound from a pistol. He says the object of the surgeon in these cases should be, not to extract the ball, but to repair the damage done by its passage; and that "in every simple pistol-shot wound it is usually not the ball which brings danger, but the surgeon with his ill-judged manœuvres."

A Model Children's Ward.

A new ward intended for children only has just been finished at the Presbyterian Hospital, in Philadelphia, being a gift to the hospital from Mrs. John Wanamaker, in memory of her mother, Harriet Eminger Brown. The ward was formally opened January 30. The following description indicates the points in which the construction of the building differs from what is customary in hospital wards:

The new ward is a two-story structure of brick and terra-cotta, with granite window sills and entrance steps. The building *is octagonal in form*, and the ground floor has a diameter of fifty two feet, and a clear height of fifteen feet. This is the main ward, and contains eighteen beds, ranged around the wall so as to face the centre. Two large open fire-places are in the centre of the room, and connect with the main ventilating shaft, which extends through the second floor and roof to the open air, where it is encased in terra-cotta work. The ward will be heated by steam pipes upon the ceiling of the basement. The walls, to a height of about ten feet, are wainscoted with encaustic tiles of various colors, and the remaining distance is plastered and finished with a hard coat of lime and sand. The windows open directly upon a porch which surrounds the building.

The second floor runs a clear height of thirteen feet. The southern half will be used as a play-room and the northern half will be utilized for the treatment of special cases. The walls of the vestibules, entrance ways, offices, etc., are finished in enamelled brick.

Dreadful Result of Carelessness in a Hospital.

At the Roosevelt Hospital, in New York, on January 31, an orderly was ordered to move a patient named Charles McClane from the second to the third floor of the hospital, where the doctors were about to perform an operation upon him. The orderly raised the elevator to the second floor and went for the patient. Having placed him in a rolling cot, the orderly moved him to the shaft, reopened the door, and, without looking to see if the elevator was there, rolled the cot forward. During the orderly's absence to prepare the patient the elevator had been sent up a story, and the patient was precipitated through the shaft down to the cellar. He was picked up and removed as carefully as possible, but died during the evening from the injuries received during the fall.

Vulvo-Vaginitis of Little Girls.

Small suppositories, about a quarter of an inch in diameter, containing each from two to four grains of iodoform, inserted in the vagina, are said by Dr. R. Potts to produce a rapid cure of vulvo-vaginitis in scrofulous children.

Benzoate of Sodium in Acute Follicular Tonsillitis.

L. C. Boisliniere, Jr., in a communication to the *St. Louis Courier of Medicine*, February, 1888, says that in upwards of one hundred cases of acute follicular tonsillitis, the following formula has been used:

Sodii benzoat.....3i–iv
Glycerini,
Elix. calisayæ.....āā f℥j
M. Sig.—One teaspoonful every one or two hours.

In the analysis of the last seventy-five cases, he finds that: 1. By the use of benzoate of sodium the disease is cured in from twelve to thirty-six hours, a great gain in time, as the average duration of the disease has been heretofore from two to five days. The average duration for the seventy-five cases was twenty hours. In private practice, when the cases could be watched more carefully, the white cheesy points have been frequently seen to disappear in from eight to ten hours. 2. The benzoate of sodium undoubtedly controls the febrile elements in the disease. 3. It may be given with impunity, even to children; he has never been able to discover any bad or even disagreeable effects from its action. 4. It is a valuable addition to the remedies used in throat affections, especially in an acute inflammatory condition of the tonsils, when applications only aggravate, and gargles increase the trouble.

Hyperidrosis.

In an article on hyperidrosis, or excessive sweating, published in the *Journal of Cutaneous and Genito-Urinary Diseases*, February, 1888, Dr. C. W. Cutler gives the following as the causes of the disease and the course to be pursued in its treatment: 1. The cause is usually a nervous one. 2. The secretion of the sweat glands seem to be controlled by the sympathetic ganglions or system of nerves. 3. The hyperidrosis is a functional affection of the sympathetic system. 4. The sweating of the extremities is usually symmetrical owing to the close relationship and anastomosis of the sympathetic ganglions of the trunk; and asymmetrical on the head and neck for want of this relationship. 5. There is but slight structural change in the affected sweats glands, and such as exists is accounted for by the hyper-secretion; the disease is probably functional and not organic. 6. The difference in appearance of the affected skin on the extremities and trunk is due to the distance from the centre of circulation, as the physiological conditions are the same. 7. Painful and tender feet, not rheumatic, are usually the result of hyperidrosis. 8. Bromidrosis is usually the result of uncleanliness — not removing the secretion promptly. 9. Nerve tonics are usually indicated in the treatment of hyperidrosis. 10. Local treatment is always indicated, and although it may not effect a cure, it nearly always relieves the symptoms.

A Queer Prescription.

The London correspondent of the *Irish Times* says: I had it yesterday, from one of the counsel retained in the case, that a very curious litigation is listed for hearing during the present term. Some two years ago a North London doctor, having a large family practice, had on his list of patients a lady long suffering from an affection of the face and jaw which baffled the arts of the faculty. She had been for some time under his care when she changed her residence from London to Newcastle-on-Tyne, but kept herself in the hands of her London doctor by letter. Finding the ailment obstinate and the patient somewhat intractable and hypochondriacal, the doctor wrote, in the end, saying he had exhausted his resources, and adding his opinion that the *edax rerum* was the only remedy. The dead language was matter in the wrong place. It proved a snare, for the lady hied herself to a local chemist, and applied for the specific as set forth in the letter. The attendant—it will be contended, through deliberate dishonesty—made up a bottle, for which he charged one dollar, and at the patient's request registered, or pretended to register, her name in the shop-book as a customer to whom the remedy was to be regularly supplied. She continued using and paying for the sham medicine for over a year and a half; and a curious point in the case will be her admission that it gave her more relief than any previous remedy employed. Coming to London for the Royal Jubilee, she chanced to meet her former doctor, who, it should be said, had told her in his letter that, being unable to do more for her, he did not feel justified in continuing the correspondence. He was astonished to find himself gratefully thanked for his final advice, and still more astonished when the lady related the facts. He wrote at once for an explanation, and advised the patient to demand the return of the large sum she had paid in fancy prices for the nostrum. The next stage of the business began with the disappearance of the assistant and the denial of any responsibility on the part of the chemist. On these main facts the case is based, but some re-

markable revelations of the human capacity for consuming doctor's stuff may be expected. The plaintiff has, it seems, been an invalid from her twentieth year, and has for the quarter of a century intervening paid for medicine alone ten thousand dollars."—*Chemist and Druggist*, Feb. 4, 1888.

Creolin in Cystitis.

The *Lancet*, Jan. 14, 1888, reports a very persistent case of cystitis occurring in a middle-aged woman, in which the pain was so constant that the patient was generally obliged to keep her bed, and in which the urine was very offensive, brownish and thick, depositing a third of its volume of pus, blood, and phosphates. After a number of different kinds of treatment had been employed by various medical men without much result, Dr. Jefsner, of Stolp, washed out the bladder with a ½ per cent. solution of creolin. This caused a burning sensation for a few minutes, after which it passed off. The next day the patient felt and looked quite a different woman, the pain in the bladder was less, and the urine much less offensive. The washing out of the bladder was repeated daily, and by this means the improvement was maintained.

American Medical Association.

The Thirty-ninth Annual Session will be held in Cincinnati, Ohio, on Tuesday, Wednesday, Thursday and Friday, May 8, 9, 10 and 11, commencing on Tuesday, at 11 A.M.

"The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States.

"Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number; *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Secretaries of medical societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective societies.

The officers of Sections are as follows:

Practice of Medicine, Materia Medica and Physiology: Chairmanship vacant; *Secretary*, Dr. N. S. Davis, Jr., 65 Randolph St., Chicago, Ill.

Obstetrics and Diseases of Women and Children: Chairman, Dr. Eli Van De Warker, 45 Montgomery St., Syracuse, N. Y.; *Secretary*, Dr. E. W. Cushing, 1 Hotel Pelham, Boston, Mass.

Surgery and Anatomy: Chairman, Dr. Donald McLean, 72 Lafayette Avenue, Detroit, Mich.; *Secretary*, Dr. B. A. Watson, 124 York St., Jersey City, N. J.

State Medicine: Chairman, Dr. H. B. Baker, Lansing, Mich.; *Secretary*, Dr. S. T. Armstrong, U. S. M. Hosp. Service.

Ophthalmology, Otology and Laryngology: Chairman, Dr. F. C. Hotz, 181 Clark St., Chicago, Ill.; *Secretary*, Dr. Edw. Jackson, 215 S. 17th St., Philadelphia, Pa.

Diseases of Children: Chairman, Dr. F. E. Waxham, 3448 Indiana Ave., Chicago, Ill.; *Secretary*, Dr. W. B. Lawrence, Batesville, Ark.

Oral and Dental Surgery: Chairman, Dr. J. Taft, Cincinnati, Ohio; *Secretary*, Dr. E. S. Talbot, 125 State St., Chicago, Ill.

Medical Jurisprudence: Chairman, Dr. E. M. Reid, 243 N. Fremont, St., Baltimore, Md.; *Secretary*, Dr. C. B. Bell, Suffolk, Mass.

Dermatology and Syphilography: Chairman, Dr. E. D. Bulkley, 4 E. 37th St., N. Y.; *Secretary*, Dr. S. F. Dunlap, Danville, Ky.

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements at least one month before the meeting.

Committee of Arrangements. — W. W. Dawson, Cincinnati, Ohio, *Chairman.*

Permanent Secretary.—Wm. B. Atkinson, M.D., Philadelphia.

Diphtheria.

Simon recommends (*Revue de Clinique et de Thérapeutique*):

℞ Acidi salicylici ..... gr. viij
Olei eucalypti ..... f ʒij
Glycerini ..... f ʒviiss
Alcohol ..... f ʒiij
Mix. Sig.—For local use, every hour.

Prizes.

The *Western Druggist* offers the following prizes:

First prize—One hundred dollars—for the best apparatus driven with power for the purposes of comminution, trituration, etc.

Second prize—Fifty dollars—for the best apparatus for continuous extraction with volatile solvents.

Third prize—Twenty-five dollars—for the best design for shop furniture for laboratory or other working purposes.

Fourth prize—Fifteen dollars—for an apparatus possessing the greatest improvements over any of the devices at present in use for compressing, coating or filling, pills, tablets, lozenges or capsules.

Fifth prize—Ten dollars—for the most simple and economical plan for fileing prescriptions.

Notes on a Recent Epidemic of Erysipelas.

Dr. G. Greene, Medical Health Officer for Ferns, reports, in the *Medical Press and Circular*, Dec. 21, 1887, that, during the months from August to November, Ferns and the surrounding district has been visited by a rather severe epidemic of erysipelas of a highly contagious nature, forty persons being attacked within a radius of three miles. The disease only affected usually the face, head, and one side of the neck, or both back and front of the chest, together with the upper extremity of the same side. The latter was the rarer but more fatal form, as it was almost invariably accompanied by double pneumonia with a pleural effusion, which also generally affected the left side. Seven, out of the nine cases affected as just described, proved fatal from exhaustion, notwithstanding all efforts made to arrest the course of the disease. There was partial paralysis of the arm in each instance. The attack lasted in mild cases seven or eight days, and in grave ones extended to five or ten weeks. The primary origin was, he believes, largely due to climatic influences; after some isoloted cases had occurred sporadically, it immediately manifested its contagious nature by attacking those in attendance or those in its vicinity. In no instance were there any abrasions of the surface in those catching the disease, nor were the original cases of traumatic origin. In the majority of cases which came under his observation, pneumonia in one or other of its forms preceded or followed the development of the erysipelatous inflammation.

As regards treatment, the author asserts that he found tincture of the chloride of iron worse than useless; while aconite and belladonna acted well in some instances by aborting the attack and curing the intercurrent pneumonia. Quinine proved useful where neuralgia was severe, and creasote when there existed much gastric disturbance. Acid tartrate of potash freely given at the outset, with flour (warmed and browned) externally applied, seemed to give the most satisfactory results in simple uncomplicated cases; whilst tincture of aconite in minim doses every third hour scored the greatest number of rapid cures where pneumonic complications existed.

The clinical value of the author's statements is rendered doubtful by his assertion that aconite and belladonna aborted the erysipelas and cured the intercurrent pneumonia.

A Chinese Doctor and His Fees.

The new district magistrate of Shanghai has taken the native doctors in hand. Lately, he sent one of his messengers to a well-known doctor, with a fee of 600 cash—about 60 cents—to ask him to visit a patient. As the messenger had strict orders not to say he came from the magistrate, the doctor was under the impression that the patient was not an official, and accordingly refused to go. Again the messenger was sent, and again the doctor refused to attend, saying the fee was too small, and that he would not go for three times the amount. The third time the magistrate sent his own card, and the doctor at once hastened to see him. On being interrogated why he had not come in the first instance, he made various excuses, which the magistrate cut short by observing that in future he would cut down the doctor's fees to such a low figure that it would not be worth his while to continue practicing. He gave the doctor the alternative of paying 5000 teals ($6000) to the Yellow River fund. The fine was ultimately reduced to 3000 teals, and the doctor, it is recorded, was very glad to get off so easily.—*London Times.*

Methylal.

Dimethylether of methylene, or methylal, is a soporific of very recent date. It is administered in doses of twenty to twenty-five grains in water, with a little syrup:

Methylal	ʒj
Syr. orange flower.	fʒss
Water	fʒj

Mix. Dose—One tablespoonful.

—*Quarterly Therapeutic Review*, January, 1888.

Insanity and Death from Fright.

It is reported from Foxburg, Pa., that a boy 12 years old, named Levi Kahl, the son of a farmer of Elk township, died on Saturday, January 14, from the effects of a fright given him a week before by some boys of the neighborhood. On the road leading from the village church to the Kahl farm there is a lonely spot in the woods where a murder was committed some years ago. At intervals stories of ghosts having been seen by persons passing the spot are told, and the locality has long been dreaded by superstitious people. On Sunday, January 8, the boy was on his way home late in the afternoon, and when it was growing dark in the woods at the alleged haunted spot. As he was passing the spot he heard a noise behind him, and turning around he saw something that he afterward, in semi-sane intervals, described as a ghost, with a head covered with many horns, jump out of the woods into the road, followed by two other figures. Two reports like pistol shots were heard, and the two figures that appeared with what the boy thought was a hideous demon fell to the ground and writhed as if in agony, while they gave vent to unearthly shrieks.

The Kahl boy fled in terror, pursued by the apparition, which followed him almost home. When he entered the house he was in such a state of nervous excitement that he fell into convulsions. He never fully recovered his mind, and his sufferings were intense up to the time of his death. Three boys, acquaintances of young Kahl, have confessed that they masqueraded at the place in the woods for the purpose of playing a joke on him by frightening him. One of the boys had fastened to his head an old tree stump, with tangled roots, which had seemed like horns to the terror-stricken victim.

Resection of the Liver.

An interesting case of removal of part of the liver is reported by Langenbuch (*Deutsche med. Wochenschr.*, Nov. 24, 1887). The patient had complained for eight years of severe pain in the abdomen, with evidence of a tumor. An exploratory incision was made, when it appeared that the tumor was that part of the liver to the left of the gall bladder, which had been separated by tight-lacing from the rest of the organ. Langenbuch ligatured the ligamentous band in several places and removed the lobe, and, although consecutive hemorrhage made a second opening of the abdomen necessary, a perfect recovery followed.

NEWS.

—It is announced that the small-pox, which was recently epidemic in Tasmania, is now completely stamped out.

—A proposal is now before the Senate of the University of Cambridge, England, to admit women to university degrees.

—Mr. George Godwin, who died recently in London at the age of 73 years, was one of the earliest advocates of sanitary science in Great Britain.

—Owing to the scarcity of doctors in Roumania, itinerant practitioners are said to be necessary, and to be in so much demand as to have treated several thousand patients during the past summer.

—Dr. Maillot, the introducer of quinine in the treatment of African fever, is to be pensioned at the rate of $1200 per annum. He is now eighty-seven years old.—*Western Druggist*, January, 1888.

—The *British Medical Journal*, Feb. 4, 1888, announces that on January 24, the fees for the degree of M.D. at Oxford, England, which were formerly about two hundred dollars, were reduced to about one hundred and twenty-five dollars.

—A local epidemic of trichinosis is said to exist in Cunewalde, near Liebau, in Silesia. The disease is attributed to the use as an article of food of small smoked sausages, some of which were found on examination to be full of trichinæ.

—By a decision rendered in the United States Circuit Court of New Jersey, the claim of the Albany Chemical Company is sustained, and the validity of their patent for the manufacture of chloroform from calcium acetate is established.—*Phar. Record*, January 15, 1888.

—A series of evening lectures on special subjects, to be given by the faculty of the Philadelphia Polyclinic at the College building, Broad and Lombard Streets, is announced. Dr. Leffmann will open the course on Feb. 28; *subject:* Office-testing of urine. Members of the profession are invited to be present.

—The *British Medical Journal* suggests that Dr. Heneage Gibbes, who has recently come from London to occupy the Chair of Physiology in the University of Michigan, may be obliged to return to England on account of the peculiar provisions of the law against importing foreigners under contract to perform labor or service in the United States.

HUMOR.

THE PRESCRIPTION CLERK generally gets the drop on everything.

MAGISTRATE:—"Have you no written document to prove that your wife is really dead?"

Peasant: "I have the doctor's bill."—*Fliegende Blätter.*

A LAY CONTEMPORARY not long ago amused its readers with the following joke: As soon as the German Crown Prince was "given up" by the doctors he began to grow better. This shows that the doctors can cure a man if they only go about it in the right way.

DOCTOR AND PATIENT.—Dr. Robert B. Morrison sends the following translation of some old Latin verses to the *Maryland Med. Journal*, Feb. 11, 1888:

When the doctor first comes the doctor an angel is he,
When the pain is relieved a God is he said to be,
But the bill sent in brings him again to his level,
The doctor is an heartless unconscionable devil.

YEARS AGO the *Seneca Falls Courier* published an amusing sketch about Horace Greely, called "a story for children," in the course of which it remarked: "The *New York Tribune* had a great many subscribers. A subscriber is a person who takes a paper, and he tells everybody else that he ought to subscribe. After he has subscribed about seven years, the editor writes to him and asks him to let him have $2.50 (two dollars and fifty cents), and the subscriber writes back to the editor and tells him not to send his old paper any more; for there is nothing in it. And the poor editor goes and starves some more."

OBITUARY.

H. T. CLEAVER, M.D.

Dr. H. T. Cleaver, of Keokuk, Iowa, died on January 11, 1888.

W. B. FARNHAM, M.D.

Dr. William B. Farnham, of Chicago, died in that city in the first week of February, 1888.

JAMES E. KING, M.D.

Dr. James E. King, one of the oldest physicians in Buffalo, N. Y., died recently at the age of sixty-five years.

H. SEYMOR STEWART, M.D.

Dr. H. Seymor Stewart, of Elyria, Ohio, who was graduated at Jefferson Medical College in 1887, died at Thomasville, Ga., Feb. 8, 1888, of consumption of the lungs. His illness lasted but a few months.

F. H. TERRILL, M.D.

Dr. F. H. Terrill died in San Francisco on January 28, 1888. He was attacked by small-pox, which has been epidemic in that city, and died in forty-eight hours. His death has been attributed to his disbelief in the efficacy of vaccination.

JOHN L. MEARES, M.D.

Dr. J. L. Meares died in San Francisco, Cal., on January 15, 1888. He was born in Wilmington, N. C., in 1822, and studied medicine in the Jefferson Medical College, Philadelphia. He went to California in 1871, and was appointed Health Officer of San Francisco in 1876.

GEORGE A. CROSBY, M.D.

Dr. George A. Crosby, a very well known and highly esteemed physician of New Hampshire, died at Manchester, January 29, 1888, of congestion of the brain, after a short illness. Dr. Crosby was born in Lowell, Mass., in 1831, and was graduated at Dartmouth in 1852. He had been President of the New Hampshire Medical Society, and was a member of the Manchester Board of Health at the time of his death.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Feb. 12, 1888, to Feb. 18, 1888:

Capt. Wm. H. Arthur, Assistant Surgeon, leave of absence extended two months. S. O. 35, A. G. O., Feb. 13, 1888.

Changes in the Medical Corps of the Navy, during the week ending Feb. 18, 1888:

Assistant Surgeon F. W. Olcott, detached from the "Minnesota" and to the "Atlanta."

Surgeon T. C. Heyl, ordered to the Receiving Ship "St. Louis."

Surgeon H. M. Martin, detached from "St. Louis" and to the "Saratoga."

Assistant Surgeon Chas. F. Webster, ordered to the Receiving Ship "Vermont."

Assistant Surgeon James G. Field, detached from the "Vermont" and to the "Swatara."

Passed Assistant Surgeon Robert Whiting from the "Iroquois" and to the Coast Survey.

Assistant Surgeon Cloner C. Tracy, resigned, to take effect immediately.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ended Feb. 18, 1888:

Eugene Wasdin, Passed Assistant Surgeon, relieved from duty at Marine Hospital, Chicago; ordered to Marine Hospital, Mobile, Ala., February 16, 1888.

Seaton Norman, Assistant Surgeon, relieved from duty at Marine Hospital, New York, to assume charge of the Service at Evansville, Ind., February 6, 1888.

WHOLE No. 1618.] MARCH 3, 1888. [VOL. LVIII., No. 9.

IS LARYNGECTOMY PREFERABLE TO TRACHEOTOMY?

BY WILLARD H. MORSE, M.D.,
WESTFIELD, NEW JERSEY.

It has been but a little more than twenty years since P. H. Watson inaugurated a new era in laryngology by excision of the larynx. It has been only fourteen years since Billroth first performed the operation for carcinoma of the larynx. And yet, since 1873 there have been no less than one hundred and thirteen laryngectomies performed. The operators have been such surgeons as Gussenbauer, Langenbeck, Thiersch, Heine, Caselli, Foulis, and others. And the results?

Hahn gives the statistics of fifty-two operations. Of these twenty-eight were successful in procuring from one day to seven months of life. This—as an interpretation of the term "successful"—is not particularly discouraging, but if we look at the results as shown from the blotted clinic-book of individual operators, we are not encouraged. Billroth, for instance, has in fourteen years done twenty-three laryngeal operations, of which five were total extirpations, seven partial extirpations, and eleven laryngeal sections. The five cases of total excision were all for carcinoma, and were all followed by death within from one day to seven months. Of the seven cases of partial extirpation, death occurred very soon in three instances. Of the ten cases of laryngo-fission, three were early fatal, and in six there was relapse or subsequent death. Of the twenty-two patients operated on, but one was really cured. Foulis's imperfect table of statistics includes twenty-six cases of total extirpation, of which all but nine suffered death or relapse. This issue is more favorable than Billroth has experienced, but not as favorable as Thiersch has, who had two recoveries out of four cases of total extirpation for carcinoma of the larynx.

From time to time we have had in the medical press more or less extensive accounts of these cases, and while too much cannot be predicated upon the results, there is much that is of interest concerning them.

Of Billroth's cases, perhaps the most important and interesting was one he operated upon in the summer of 1879. He removed from a woman at that time the pharynx, the cervical portion of the œsophagus, the larynx, a part of the trachea, and all of the thyroid gland, for a cancer of the pharynx involving the posterior portion of the larynx. He first did a prophylactic tracheotomy, and performed the major operation nine days later, after introducing the canula tampon of Trendelenburg. The incision was made along the anterior border of the sterno-cleido-mastoideus, and immediately upon opening the skin the operator found that the tumor was more extensive than he had supposed. Step by step he proceeded until the whole work was done. An artificial œsophagus was placed where the cervical portion had been removed, and aliment was introduced through it for four weeks, during which time the patient made a fair improvement, quite like recovery. At the end of that time this tube was removed, in the hope that the pharynx would unite with the lower portion of the œsophagus and form a true substitutive canal for the passage of food. After the removal of the tube, however, deglutition was accompanied by suffocation and vomiting, causing retraction, and necessitating the passage of bougies. In the sixth week a false passage was made in the peri-œsophageal tissue. After this, death from pericarditis soon ensued.

Langenbeck, who has operated three times, has a similar procedure. The following are the steps of his operation: First of all, tracheotomy is performed, and Trendelenburg's canula is introduced; then an incision is carried from the body of the lower jaw, midway between the angle and the symphysis, toward the greater cornu of the hyoid bone, and thence along the anterior border of the sterno-mastoid muscle as far as the upper extremity of the tracheotomy incision. Next, the submaxillary gland is removed, the lingual artery tied, and the hyoid muscles detached. The pharynx is then laid bare, and can then be dissected out, the larynx meanwhile being drawn up to the opposite side. There are two principal dangers in the operation; peri-œsophageal phlegmon, and pneumonia, from the introduction of foreign bodies into the air passages. Langenbeck is not on record as favoring an artificial œsophagus, but Kolaczek, who has had a successful case, had his patient nourished through such a tube for eight weeks. The removal of this tube is often followed by bad results. Langenbeck, and as well Koenig, of Göttingen, and Gussenbauer, of Prague, lost their patients when the tube was removed, pneumonia being set up by the passage of food into the lungs. To avoid this danger, Thiersch has proposed preliminary establishment of a gastric fistula.

The entire history of an interesting case, in which Dr. Foulis, of Glasgow, performed extirpation of the larynx, was withheld until the death of the patient. It appears that at the time of the operation, there was latent disease of the lungs; but the patient, a young man, survived for seventeen and one-half months afterwards—a longer period than in any similar case, so far as I know. During this time he enjoyed a useful and comfortable existence, working eleven months as a telegrapher, wearing the artificial larynx all of the time, day and night. Toward the end of the year, cough, hemoptysis, and night-sweats began to occur, and the interior of the trachea showed extensive ulceration, presumably tubercular. Death resulted from the pulmonary disease, and the operator has always expressed himself as positive that the extension of the malignant disease was arrested.

Dr. J. Solis-Cohen, of Philadelphia, has proposed, where the operation is practicable, a modified laryngectomy, by which the entire respiratory portion of the larynx can be removed, and the greater portion of the thyroid cartilages be left undisturbed to perform their function as shields. It is applicable to both the unilateral and the bilateral procedure; and not less than five distinct advantages are claimed for it. These are: (1) the rapidity with which it can be performed, with comparative safety to the patient; (2) the small size of the wound; (3) the preservation of the attachment of thyroid and hyoid ligaments and the several muscles; (4) the retention of the functional structures for deglutition; and (5) the leaving of a firm, natural support for the adjustment of artificial substitutes for the larynx. This modified method is so comparatively recent, and has been performed only upon the cadaver, that it is impracticable to pronounce on its full availability. It would seem from the past history of laryngology that laryngectomy is not yet a success or attended with any certainty of hope, all operations having given good results, but all patients suffering recurrence. Individual operators have done admirably, daringly and nobly, but the time that has elapsed since 1866 is not sufficient to have done more than suggest the possibilities of the operation. I can find, in 113 cases, only 29 in which the patient has survived six months, and yet only 62 (or perhaps 66), of the laryngectomies were for carcinoma of the larynx.

Since fully one-half of the cases of cancer of the larynx are unilateral, partial laryngectomy is in some favor, especially in England, where it is claimed that much better results are obtained from the operation than from that of total excision. This may well be, if cases are to be selected, partial laryngectomy having peculiar advantages in unilateral and intra-laryngeal epithelioma, and in recent, non-infiltrating sarcoma. It is obvious that where the cancerous implication is extensive it is useless. Perhaps if we were to have a "rule" in the matter, it would be best to do the entire removal. It promises as favorably, if not better than partial removal; but such promises are like those of the fortune-teller. There is no even chance of life, and if it be granted, it is a life of anxiety, dread and abject misery.

Beyond doubt, tracheotomy promises better results, and, moreover, fulfils all that it promises. It has been a means of saving patients by death from asphyxia so long that it needs no advocacy; but the indications for its performance in a wider field of usefulness may require a word of encouragement and a basis of establishment. There is virtually no other palliative treatment either in the first or second stage of cancer of the larynx. It relieves the patient from immediate danger to life; and when the morbid growth is so situated as to be beyond the

reach of intra-laryngeal treatment, there is no preferable method of procedure. It may, however, be stated as a cardinal law, that the operation is not to be performed unless there is immediate danger from suffocation or dysphagia. It is adopted as a preliminary measure of safety when thyrotomy is to be done, and results in the avoidance of suffocation, and the accession of greater certainty and safety.

In 1863, Czermak recommended infra-thyroid laryngotomy; but it was not till two years later that Burow, of Kœnigsberg, carried it out. In this operation, as also in the combined method, a preliminary tracheotomy is performed.

Thus we may recognize that, after the abandonment of laryngoscopic treatment as impracticable for any reason, it is a surgical duty to employ tracheotomy as a means of arriving at mechanical or chemical treatment in preference to extirpation, either wholly or in part.

The following notes of two cases seem to me instructive as showing the power of tracheotomy in facilitating recovery and averting death.

A. D. C., a French sailor, 43 years old. Had had syphilis nine years before. Though the treatment of the secondary symptoms had been successful, he had suffered from throat symptoms, which had latterly become chronic. On coming under treatment, the pharynx was found to be extensively ulcerated, and the laryngeal and pharyngeal mucous membrane greatly thickened and sensitive. He was placed under constitutional treatment, but continued to fail. In the second week he coughed up several bits of necrosed cartilage. This led to a definite understanding of the emergency which soon arose. A succession of laryngeal spasms occurred, and in a third or fourth intermission I found suffocation so imminent that tracheotomy was performed. Subsequently the patient came under the care of his family physician, receiving constitutional treatment, and nothing more was heard of him till some ten weeks later, when he came to the city to have the tube removed. When this was done, there was no delay in the closing of the opening in the trachea. By arresting a fatal issue, time had been gained for efficient treatment, and the air being diverted from the diseased larynx, there was nothing to hinder cicatrization. It may be said that syphilitic ulceration and a carcinomatous or a papillary growth are entirely dissimilar. Admitting this, the former is quite as apt to occasion laryngeal stenosis as the latter, and it is, in a surgical sense, a more serious matter than carcinoma. Total extirpation for syphilitic ulceration would have been out of the question altogether, thus showing the value of the tracheotomy.

The second case was that of E. H., 35 years old, a taxidermist. He had had some little difficulty in deglutition for about a year, and had been hoarse and suffered from a slight cough for two or three months. There was no pain in the throat, and he applied for treatment of suppuration from the right middle ear. A laryngoscopic examination showed the epiglottis to be thickened, and a growth of the shape and size of a Lima bean projecting from the right side of the ventricular space. The vocal cords showed no indications of encroachment. Circumstances removed the case from observation until nine months later, when the laryngoscope showed the arytenoid cartilages infiltrated. (During this time the growth had been clipped.) He was advised to enter the hospital and have the operation of tracheotomy performed. This advice was heeded, and an ordinary tracheotomy canula was introduced. A dissection of a portion of the growth revealed the characteristics of epithelioma. At present writing (five weeks since the operation), the young man breathes easily through the tube, and there is great improvement in deglutition, cough and general health. It has since been learned that the surgeon who performed the clipping pronounced the growth papilloma. May not the intra-laryngeal operation turn a growth from papilloma to epithelioma, as suggested by Browne, of London? Further, may not this have been the case with the Crown Prince of Germany? Professor Virchow pronounced the growth a papilloma at the first, and Virchow is not an erring microscopist. It is now declared to be carcinoma. Did the operations performed on the Prince metamorphose it; and, if so, is that not another argument in favor of tracheotomy, with thyrotomy, if necessary, following?

The amelioration of the laryngeal condition which follows tracheotomy is striking, if the canula is inserted for syphilitic ulceration, carcinoma, papilloma, or for laryngeal phthisis, as Prof. Beverly Robinson recommends. Extirpation of the larynx is contra-indicated, not only because of the ultimate almost uniform failure of that operation, but because the greatest amount of good to be obtained from it cannot equal the fortunate effect of prolongation of life from simple tracheotomy.

It may be a matter of interest at this moment, *apropos* of the two cases of leprosy now quarantined in a Philadelphia hospital, to take note digressively of the fact that the larynx of a leper is pathologically interesting and peculiar. The air-passages undergo changes, revealed to the laryngeal mirror as a thickened and congested epiglottis, a stenosis of the upper aperture, a tumefaction of the ary-epiglottic folds; the mucous membrane is dark red, the vocal bands of a dirty yellow color, and there are other changes, more or less persistent. Laryngeal disease occurs in nearly all cases of leprosy, provoking the husky voice of these unfortunates, which was noted as early as 1526, when Hans von Gersdorf, in his *Feldbuch der Wundarzenei*, remarked: "Das erst zeychen ist die heyssere in der stymm, und red, enge des stems." Elsberg, in 1879, thus described a leprous larynx as found on autopsy:

"The palato-glossal folds and the pharynx show a few nodules. The tip of the epiglottis is thickened to the extent of one-fourth inch. At base an abnormal yellow infiltration and superficial ulceration. Orifice of glottis presents an oval, puckered appearance. Mucous membrane covering vocal cords shows an almost uniform nodular thickening."

Shall laryngology ever know a time when the knife shall deal as willingly with laryngeal leprosy as it now deals with laryngeal syphilis and carcinoma?

PUERPERAL SEPTICÆMIA.

BY JAMES E. FREE, M.D.,
BENEZETTE, ELK CO., PA.

The REPORTER for September 3, 1887, contains a *résumé* of the instructive discussion on puerperal fever, which took place at the recent meeting of the British Medical Association in Dublin. A careful reading of this paper shows that wide differences of opinion exist among English authorities as to its nature. The disease is not liable to change its character very much by reason of climate and location. At least it appears to me that its features as described by physicians across the ocean are the same as American observers notice.

Playfair is a vigorous champion of the septic theory. He makes a distinction between puerperal septicæmia and puerperal fever, the latter term he abhors, although maintaining that the puerperal disease is identical with surgical fever. He says there are conditions due to chills, malarious influences, meterological states, etc., which present analogous phenomena, but are not related to the disease proper. His dictum is that puerperal septicæmia is the result of septic absorption through the genital tract, and it might be inferred from the language used that if a puerperal fever arises by the introduction of poison into the system through any other channel it is not to be called by the name common to the first.

The exact qualities of the material which has such an affinity for the generative organs of women are not stated, but since the effort is made to exclude so many possible sources of contammation it must have a multiple origin. The septic influences of the ordinary lying-in room are not similar to those which antisepsis is used to guard against when the accoucheur comes to his patient from the pathological laboratory. Whatever the cause may be, it is agreed that in conflict with bichloride of mercury solutions it is at once shorn of its strength to do evil. Therefore the partisan of this theory, like the Scribes and Pharisees, hold traditions in regard to the washing of pots and cups and many other such things. They say it is desirable at an early stage of labor to thoroughly syringe the vagina, and sponge the vulva with an antiseptic solution. And again when the head is distending the perineum the external genitals should be sponged with the solution. Why these rules are important is not entirely clear. If the atmosphere is so loaded with the germs of puerperal disease, absolute safety cannot be obtained short of an apparatus similar to that of a diver for both patient and obstetrician, and then have them immersed in a bath of bi-chloride of mercury solution.

Labor is not usually a rapid process, and the time that intervenes between the two bathings may be some hours. It can hardly be supposed that the first application thoroughly protects the genital organs until the second is in order. The contact of the antiseptic solution at best only continues for a few minutes, and if it does exert the specific action claimed for it, the genital tract will shortly be in a condition to absorb the septic material. If there is no danger to the patient except by means of the touch of the nurse and accoucheur, what use is this long prophylactic treatment? The cause of puerperal septicæmia, if it is carried into the vagina by the hand, must be something of the nature of the vaccine virus or syphilis. And if this disease is like surgical fever, we ought to meet with cases bearing a remote resemblance to it in the non-pregnant. The vari-

ous operations undertaken for the relief of diseased organs of reproduction, lead frequently to a rise of temperature and its accompanying features. If the same material was absorbed in this case that previously caused puerperal septicæmia, would the patient be in the same condition as her pregnant neighbor? The difference would be what pregnancy adds to the one.

Robert Barnes, of London, finds the cause of the disease in the patient. First, he sees a powerful influence at work to modify the constituents of the blood, in the shape of an acute process of growth; then, secondly, there is labor with its tension and strain of the nervous and muscular system; and, thirdly, the necessity for the large excretion of useless material. It is plain that whatever hinders nature's efforts to establish the normal relations of the parturient woman's organs and blood must aid in the establishment of puerperal fever.

In many labors absorption is improbable when the head is descending and stretching the perineum, because of the secretion which bathes the canal; and it is not plain why there is a necessity to soak the vulva in a mercurial solution when every blood vessel, muscular fibre and lymphatic structure is engorged to the limit of its capacity. No absorption is likely to take place when such obstruction to the circulation exists, and the rush of amniotic fluid, blood, etc., which accompanies the child into the world, would do as much toward getting rid of poisonous material as antiseptic douches. The hands of nurses and physicians should occasionally convey this septic material to the gravid woman's blood. Is surgical septicæmia possible from such a cause while the woman is carrying her child?

If a patient be confined in a house which is scientifically constructed, the mother ought not to require the rigid application of this system. Every obstetrician lays stress upon proper ventilation, sewer connections, etc., and some insist upon saturating the atmosphere with chemical agents capable of destroying the germs of disease.[1] The washing of the air is recommended by some; but what are the potent results to be obtained by these measures if the root of the evil is to be found on the hands and instruments which come into contact with the genital tract?

It is said that obstetricians may attend a case of labor immediately upon coming from the dissecting table, if they take the precaution to change their outer clothing and wash in the convenient mercurial solution. That washing is regarded as a preliminary step under such circumstances presupposes that the exhalations, and minute particles of decomposed cadaver, may be the cause of the disease. The hair of the individual who is engaged at the dissecting table will carry the odor of the dead, and why not the germs of puerperal septicæmia? But it is not insisted that he wash his hair with the mercurial solution; this is perhaps an oversight which the true disciples of the theory will correct, as soon as their attention is called to the fact. When a man absorbs the poison from a dead body into his system, it gives rise to a series of well recognized phenomena; and why should a woman infected with the same material be said to suffer with a disease which is equivalent to surgical fever? In the case mentioned in the discussion of the physician who infected sixteen patients with his forceps, after taking elaborate antiseptic precautions in other directions, there must have been criminal neglect in the care of his instruments; and it is wonderful that before this time others, besides his pregnant patients, have not been sent to the bourne from whence even antisepsis cannot bring tidings. The first patient upon whom he used the forceps after they became capable of transmitting puerperal septicæmia, would doubtless smear them with a conglomerate composed of the debris of the pregnancy, and if there was anything on the blades which warmth and moisture could revive, it might stay in the genital canal. How any physician could put a pair of forceps in their case without making some effort to clean them is inconceivable—it would be beastly. Let us suppose that he wiped off the blood-stains and put the forceps in their place. The septic material in the vagina of his patient would find a convenient nidus in a blood-clot. Part of this clot might pass out at the ostium vaginæ, become desiccated, and perhaps even so finely divided by the attrition of the bedclothes, the patient's body, etc., as to be capable of diffusion into the atmosphere of the room. Such being the case, there would be nothing to hinder the passage of the septic material into the lungs.

Should this actually occur, would the blood be contaminated during the process of oxygenation, or would endosmose and exosmose be carried on in sweet oblivion of the germs of puerperal septicæmia? And if the blood in the lungs refused to take up the septic material, why should the blood in the genitalia, which is the same kind of blood, be so ready to do so? At the time the forceps

[1 This is a physical impossibility.—Editor of REPORTER.]

were used the woman is supposed to have been in good health, and necessarily some space of time would be required to elapse before its absorption and development in the blood of the victim. Culture experiments teach us that the process is not instantaneous, and if time is necessary, the physician and his forceps may be far enough away. Not to stretch the imagination too far, the same forceps which are accused of lighting the fire of puerperal septicæmia in one case, may have assisted at a delivery that ended happily. The second woman is perhaps said not to be susceptible to the poison. But the third gravid uterus into which they are thrust manifests symptoms similar to the first one. Now how has the poison been admitted to the third woman's blood? Its immersion in the secretions of the first woman's vagina, who manifested the disease later, could not have infected them a second time; because she was healthy at the time, and by the time she could have smeared them with the material to cause puerperal septicæmia, they were out of harms way. Therefore, if the disease was propagated by the specific germ of the disease on the forceps, it must have all depended through the whole series of sixteen, upon the supply on the forceps in the first place. If such were the case there ought to have been a descending scale of virulence noticed as the poison became scarce.

A forceps which would not be scoured by sixteen successive smearings with blood, mucous, amniotic fluid, etc., might perhaps be made harmless by washing in a mercurial solution. The poison introduced by the forceps might have come from a source peculiar to the environment of acccucheur and patient at the time of delivery. To say the least, the subject is somewhat obscure; but every physician ought to be fully persuaded in his own mind by a study of the subject in all its bearings before attempting to treat the disease.

The theory of Robert Barnes seems to me to offer the most satisfactory explanation of the phenomena witnessed. As he pointedly insists, season has much to do with the prevalence of puerperal fever, and because in the cold inclement months of the year it is more difficult to maintain an equable supply of pure air, it rages especially during that time. When houses can be thrown open and the summer air allowed to penetrate to every part, the unhealthy influences of dampness, sewer-gas, and all the ills which depend upon defective sanitation are much lessened in virulence, and the safety of the newly made mother more perfectly insured.

THE TREATMENT OF STERILITY DUE TO ATROPHIC UTERUS AND STENOSIS.

BY W. F. McTAGGART, M.D.,
SAN FRANCISCO, CAL.

In connection with this subject, the following cases may present some features of interest:

A woman, aged 33, nullipara, married ten years, anemic, and much emaciated, consulted me for dyspepsia and leucorrhœa. The latter led to an examination of the uterus, which at once disclosed the cause of the failing health. It was a marked case of atrophic uterus and stenosis. The treatment instituted was rapid dilatation of the cervix and intrauterine faradisation, to nourish the organ by stimulation. The canal was kept patent by the use of sounds for three months. At this time the patient's health was greatly improved, and she was lost sight of for six months. She returned at the expiration of this period with premonitions of her former malady. Again electricity and dilatation were brought into requisition, the latter being made effective by the aid of four free incisions, postero-anterior and bilateral, which were carried well up to the os internum, one of them passing through. The cervix uteri was then packed with cotton saturated with solution of perchloride of iron, to check the hemorrhage, of which there was considerable. I kept the patient in bed two weeks, after which thorough dilatation was carried out at my office for five weeks longer. Two months from the date of the operation I dismissed the patient from my care with her health remarkably improved. Nearly a year after leaving me, she became pregnant; and now, eight years since I last saw her, in soliciting my interest in the health of a sister, she writes that her condition has remained unusually good, and that she is the mother of three fine children.

Another subject of atrophic uterus with stenosis, precluding pregnancy, was a married woman who gave birth to one child when she was only nineteen years old. Seven years afterwards she consulted me for uterine "trouble," having had no children during this interval. She gave a history of much pain endured for more than half these years, and was now suffering from nervousness. She had had the cervix dilated, and had been treated by many physicians, who gave as many different names to her malady. She was "tired of seeing doctors," but suffering induced her to make "just one more

effort to get relief." Examination proved the cervix to be greatly elongated, and so occluded as to suggest atresia due to laceration in childbirth, as evinced by the presence of bilateral cicatrices. The uterus was undeveloped, and there was considerable tenderness of the ovaries. This is an apparently contradictory condition, since congestion of the appendages usually leads to extension of the irritation, and increase, rather than diminution, of the volume of the womb. Electricity was employed, together with gradual dilatation, for a period of three months, with but little improvement. An operation, which had been proposed as the first requisite and deferred in deference to the patient's objections, was now performed for the elongation by passing a No. 8 sound, no larger being admitted, and cutting down toward it transversely, taking out a wedge-shaped piece anteriorly, and a corresponding one posteriorly, not reaching quite to the sound, taking care to leave an interspace sufficient to maintain union, and then bringing the wounds together with wire sutures. Subsequently incisions were made to complete the cure, and two children, and possibly more, were born to the patient afterward. A slight laceration, which readily healed, attended the birth of the first child. The second was born without any untoward results.

The next case which I will mention was that of an unmarried woman, 29 years old. She had suffered several years from dysmenorrhœa, shedding large shreds and clumps from the age of twenty-three to nearly twenty-eight years, when her menses ceased. She consulted me about one year later. Nervousness, emaciation, hysteria and a distaste for food characterized her condition. Examination revealed an almost shriveled state of the uterus, with occlusion of the os. Electricity, dilatation and incisions were employed, with the result of restoring her health to a considerable extent and re-establishing the menses. But five years of married life thereafter brought no issue.

Another case was that of a married woman 36 years old, from whom a uterine polypus had been removed some five or six years before. For more than three years she had suffered severely with pelvic pains, pains in the thighs, copious leucorrhœa and great nervous prostration.

The last nine months she could not leave her bed. Owing to her reduced condition, I desisted from operating until her strength was somewhat restored. This was accomplished by means of iron, strychnine, phosphorus and quinine, together with the induced current per vaginam. Nourishment: oatmeal, eggs, milk and oysters. Six weeks of this treatment fostered a condition to warrant me, as I thought, in operating by incisions and dilatation. Convulsions and some inflammation of the uterus followed the operation. An apparently critical condition existed for a few days, then a rapid recovery followed; she afterwards became pregnant, but aborted at nine weeks, and was apparently incapable of pregnancy thereafter, at least for five years, when I lost knowledge of her. After the abortion her menstruation was regular, and her health comparatively good.

Other cases of atrophy of the uterus which have responded satisfactorily to the above treatment might be recorded, but the instances here presented will serve my purpose, and are designed more to illustrate than to attest the value of the means here adopted as curative measures. Regarding the agents employed a few words touching the use of electricity may prove suggestive. Good results can be secured only by a prolonged use of the Faradic current; the galvanic being less efficient in atrophic structures. It must be persevered in for a few months at least, and perhaps repeated after the lapse of a month or two. The current should be as strong as the patient can well tolerate; the negative current being employed intra-uterine, or, if that is impracticable, to the os with the cup-shaped electrode; the positive over the abdomen and the lumbar space. Unfortunately each application should occupy from fifteen to twenty minutes; a fact obviously an obstacle to the busy physician, unless he have plenty of assistants.

As to the success attending dilatation with dismissal of the patient a few days after, as reported by some leading gynecologists, I have but rarely been able to attain it. Whether the cervix be incised or not, lacerated by divulsion or not, I have found a tedious use of sounds, in some instances extending over months, necessary to outrun the resultant congestion and render the passage patulous. Patients dismissed in from two to three weeks after this operation for stenosis have returned to me in such number, requiring a repetition of the treatment, that I cannot from my own experience—whatever that of others may be—advocate a summary disposal of such cases. My course is to thoroughly dilate, make incisions when necessary to aid, keep track of all structural changes; and, when normal with patent canal, dismiss my patient with a feeling of

security that the cervix is insured against future closure.

The consumption of time, the attendant expense of the service, and the irksomeness of the routine, all suffered by the patient, doubtless militate against the thorough carrying out or completion of the treatment. But as permanent results, and not temporary effects, urge our patients to judicious efforts, we can generally reconcile them to the tediousness of the procedure by instructing them as to its nature, and explicitly directing them to the object which is sought to be achieved.

Regarding the operation for elongated cervix, it has the merit of being conservative as well as exceedingly valuable. The section to be removed may be proportioned in area and depth to the elongation. But it is surprising what an amount of contraction is effected by merely snipping out a small piece on either side or around the cervix, and then allowing it to heal. By this operation, which I have for several years successfully adopted, not only is amputation of the cervix for elongation avoided, but better results are secured, inasmuch as the integrity of the os is protected, and in consequence of the coaptation and the result of the healing, the main object desired—that of shortening the neck—is accomplished.

HYSTERO-EPILEPSY SUCCESSFULLY TREATED WITH CHLORIDE OF GOLD AND SODIUM.

BY C. L. DODGE, M.D.,
KINGSTON, N. Y.

Case I.—Miss D., aged 17, pale complexion, slight figure, weighing only 90 pounds. When 7 years of age, she had chorea, which lasted for a year, but finally yielded to treatment. Menstruation came on at 13 years of age, and she always suffered greatly at these periods. The family history is quite remarkable; her father has had epilepsy for years, her mother had chorea when a child, and a brother has slight choreic twitchings of the left side of the face at the present time. When about 15 years of age, the patient had the first "nervous spell," as they termed it, which was brought on by anger at being refused permission to go to a ball. This attack, from what I could learn, was purely hysterical. After it, so-called fits occurred from time to time, increasing in severity and frequency, and assuming more and more the character of epilepsy. This state continued for two years, gradually growing worse, and all treatment up to the present time being futile. When I first saw her, she was having from two to ten fits a day, and one day she had forty. The paroxysms were very severe, often requiring two or three persons to hold her in the bed and to prevent her from injuring herself. There was sudden and complete loss of consciousness, pale face, eyes partially opened, pupils sluggish; she would bite her tongue and hands, and strive to bite her friends, would tear her hair out, and at the commencement would cry out with pain—at least she insisted that she had pain after her attacks were over. Her features were distorted and her convulsions, which were sometimes tonic, sometimes clonic, were more marked on one side than on the other. She manifested great muscular strength at these times, although she was very slight and delicate. She evinced no feeling, and firm pressure over the ovaries produced no effect; neither arresting the paroxysm nor giving rise to pain. These attacks lasted from three to ten minutes, with intervals of ten to twenty minutes. The number of paroxysms at any given time varied; sometimes she would have only four or five, and on one occasion she had as high as forty in one day. After having apparently exhausted her strength, she would fall into a heavy, half comatose sleep, followed by headache, dulness of intellect, and great irritability of temper. She had been treated with morphine hypodermically for a long time, which had the effect of relieving the spasmodic character of the attack and inducing sleep. Generally, on awakening she would appear rational and remain so for the rest of the day, but sometimes as the effect of the morphine wore off, she would have a return of the paroxyms. Chloroform would also control them; but for a short time only. Bromides seemed to have no effect whatever, which led me to think the disease was not epilepsy. Tonics of all kinds were tried; but they had no effect on her appetite or general health, nor on the nervous disorder. At last, I prescribed pills of chloride of gold and sodium, each containing $\frac{1}{20}$ grain. One was taken three times a day. The first box contained sixty pills, and before these were all used up she showed decided signs of improvement, her appetite returned, she gained flesh and strength, and returned to her work—that of a milliner—and seemed as well as ever. She continued the use of the medicine for several months and had no return of the malady. Nearly a year afterwards her mother told me she had had a slight attack, but it was so mild that she did not send for me. I directed

her to renew the prescription for the pills of chloride of gold and sodium, when she at once began to improve, and has had no return of the trouble. This is more than three years ago.

Case II.—Mrs. K., aged 28; dark complexion, short, stout figure; has one child 8 years of age, and has never been pregnant since; her menses are regular, but she always suffers great pain at these periods. Her menses appeared at thirteen years of age. At her first menstrual period she suffered greatly, and had fits for a whole day. She often has "fainting spells" at these periods. Her mother when young was subject to fits also. September 2, 1887, on the first day of menstruation she was seized with a fainting fit at the water-closet; everything grew dark, she said, and in trying to reach the house she fell and bruised herself somewhat. I saw her shortly after she fell, and found her unconscious, pale, cold, eyes closed, and pulse feeble. Several small doses of brandy and water were administered, followed by hot applications to the feet and legs, with inhalations of ammonia and the usual remedies employed in an attack of syncope. She rallied in a few minutes, when she complained of intense pain in her left side in the region of the ovary; pressure over the spot was painful, but had no other effect. I then gave her a full dose of morphine, and left directions to repeat it as often as necessary until the pain ceased. The morphine relieved the pain but affected her head unpleasantly, making her delirious. This all disappeared as soon as the effect of the drug passed off. She remained in bed for several days, after which she seemed as well as usual. Four weeks from this date, I was again summoned to find her in convulsions. Her menses had just appeared, and I was informed that before she became unconscious she had complained bitterly of pain in her left side extending up to her heart, which seemed to smother her. The convulsions were more tonic than clonic; the eyelids were closed, the eyeballs rolled upward, the pupils sluggish and somewhat dilated. Her mouth was closed, and respiration seemed to stop. Pressure over the ovarian region had no effect. She made no response when spoken to, and seemed not to hear or see. This attack lasted fifteen or twenty minutes, after which she recovered consciousness and complained of pain in her side. Mustard was applied to the side, and morphine administered for the pain. She now took to her bed and became somewhat hysterical, lost her appetite, complained of fugitive pains, and grew very irritable. She had these attacks frequently, sometimes two or three in a day. She was also troubled with nausea, perverted taste, and spasm of the throat. Usually just before a paroxysm, she said she felt a choking sensation in her throat, and a sense of impending suffocation. Borborygmi and tympanites were present, also a burning and itching of her face, with coldness of the hands and feet. At times there appeared to be a certain amount of swelling of the abdomen, and of the inner sides of the thighs. In the more severe attacks she would bite her tongue, and roll herself around the bed, so that she had to be restrained. After the attack she passed a large quantity of clear, colorless urine. At other times she imagined she was unable to empty her bladder. In addition to these symptoms she now complained of a continuous pain in the left side in the region of the ovary, with a slight amount of swelling. A uterine examination was made, but revealed nothing except a certain amount of tenderness and slight swelling. The temperature was never over half a degree above normal, and, notwithstanding the fact that she ate nothing, she apparently lost little flesh. She remained in this condition for eight weeks, absolutely refusing to get out of bed, saying she was too weak and suffered too much pain. Numerous remedies were tried with no apparent effect; bromides in large doses, morphia, chloral, valerianate of ammonia, quinia iron and strychnia, wine of coca, brandy, aromatic spirit of ammonia, viburnum, camphor, etc. Carbolic acid and calomel were given in small doses for the nausea, which at times was very annoying. Finally, after eight weeks of treatment with these remedies, I abandoned everything and gave her chloride of gold and sodium only, in one-twentieth grain doses three times a day, when to my surprise and gratification she began at once to improve, and in less than a week she got up, dressed herself, went to the table and ate with the family. She took this medicine for two weeks, and nothing else, and has remained free from convulsions from that time to the present.

These were certainly severe cases. That they were not epilepsy I think is perfectly clear. Neither can I consider them hysteria, pure and simple, as we ordinarily meet with it in this country. A recapitulation of the symptoms in both cases shows absolute loss of consciousness, insensibility of the pupils to light, biting of the tongue, followed by heavy half-comatose sleep, and on waking, headache and general soreness. This all resembles epilepsy; but it must also be added, that the face was always pale, globus hysteri-

cus was present, and after the paroxysm passed the patient voided a large amount of pale, clear urine.

Prof. H. C. Wood says:[1] "As contrasted with the characteristics of the epileptiform convulsion, those of the hysterical convulsion are: the peculiar disturbances of consciousness, the presence of emotional disorders, and the tendency of the muscular contractions to simulate in an exaggerated form natural movements, and to become tetanic. Persistently clonic spasms pertain especially to the epileptiform convulsion, whilst tetanic rigidity is indicative of the hysteroidal."

Mills states[2] that two forms of hystero-epilepsy are recognized: 1. Hystero-epilepsy with separate crises, in which the symptoms of hysteria and epilepsy appear completely independent of each other, and in attacks perfectly distinct. 2. Hystero-epilepsy with combined crises, in which hysterical and epileptic symptoms are commingled in the same attack. In the first variety the same patient is the victim of two distinct diseases, hysteria and epilepsy. The second is hystero-epilepsy proper, and the term hystero-epilepsy should be confined to this form. Much confusion would thus be avoided. I believe, with Mills, that this disease is hysteria—not epilepsy. Hysteria major is the true term to apply, although in many respects the disease simulates epilepsy very closely, as pointed out above. The fact that the bromides have little or no effect is strongly against epilepsy.

I would also call attention to the temperature record in these two cases. At no time did the thermometer show a rise of more than half a degree above normal, which, according to Richer, is an important point in the diagnosis. It is stated by this observer, that an elevated temperature belongs to the epileptic state; while in hystero-epilepsy the temperature rarely rises above 100° F.

—The *Lancet*, Feb. 4, 1888, announces that Agostino Bertani, well known in recent history as surgeon-in-chief to Garibaldi, in the general's campaigns for the freedom and unity of Italy, has just been honored with a memorial tablet inserted in the façade of the Hotel Italie in Rome, where he died in the summer of 1886. Another of Italy's medical worthies receives similar recognition at Bologna, where, on the 2d inst., Dr. Magni, "the greatest Italian oculist since Vacca," had a commemorative tablet unveiled in his honor at the instance of his surviving colleagues.

Society Reports.

MEDICAL SOCIETY OF NORTHAMPTON COUNTY, PENNSYLVANIA.

Report of committee on the

Rights and Duties and Powers of Coroners.

The committee appointed by the President of the Society to investigate the law in reference to the rights, duties and powers of coroners, respectfully reports as follows:

The question presented to them in the resolution is one to which it is difficult to give a definite and comprehensive answer. With the exception of two acts in reference to fees applying to Philadelphia only, there is no act of Assembly in Pennsylvania prescribing the rights, duties and powers of coroners. The office of coroner with the laws relating thereto was incorporated into the laws and customs of this commonwealth from the laws and customs of England, together with all those fundamental principles of our laws, which constitute what is known as the common law.

The duties of the coroner must, therefore, be learned from the common law, so far as in reference to this subject, it has been retained in the laws of this State.

The decisions of the courts, and, particularly those of the Supreme Court, being the only sources from which we may derive authoritative opinions respecting any disputed points of the common law, it is to these decisions that we must look for an answer to the question proposed in the resolution.

The reported decisions as to the duties of coroners are not numerous. Whether this meagreness of litigation on this subject in the court of last resort has been the result of a generally faithful performance of duties by coroners, who were not, therefore, called into courts to answer for any derelictions, or the result of public indifference to the acts of coroners, however, illegal these may often have been, your committee is not able to say.

In the case of Lancaster County *vs.* Dern, 2 Grant, 236, etc., the Supreme Court said: "There is no law that we are aware of, which defines all the subjects of inquiry for the coroner's inquest. It is true that the Statutes of 4 Ed. I., sec. 2, and 3 Herr. VII., (a portion of each of which statutes are in force with us), command the coroner to go to the place where anyone is slain, or has suddenly died, and inquire into the cause of death; but it has been observed that these statutes, being wholly directory, and in affirmance of the commom law, the coroner is thereby not

restrained from any branch of his power, nor excused from any part of his duty, not mentioned in them, and which was incident to his office before."

From an investigation of the cases reported your committee is of the opinion that the coroner not only may, but also should hold inquests:

1st. Where it is known that the deceased died from violence inflicted by another, or there is suspicion that the deceased died in such manner.

2d. Where the deceased committed suicide, or there is suspicion that he did so.

In cases of death comprised under these two heads it will hardly be disputed that the coroner ought to hold an inquest.

"It is the duty of the coroner to hold an inquest in all cases where there is cause to suspect a felonious killing of the deceased." Northampton County *vs.* Innes, 26 Penn. St., 156.

If such cases should be taken from his jurisdiction, his function would be entirely gone, and his office would become useless.

There are two more classes of cases in which it is not so easy to define the duties of the coroner. These are:

1st. Cases of sudden death, which, though it has been without violence, has proceeded from no known cause, and was not preceded by any known illness or ailment.

2d. Cases of death from the effects of an accident.

It is in these cases that doubt frequently arises, and objection is made to an inquest on the ground that it imposes costs on the county, and harasses the feelings of the relations and friends of the deceased, while at the same time it does not bring any corresponding advantages to the public.

Where the death is sudden, without violence, proceeding from no known cause and not preceded by any known illness, the coroner has jurisdiction, and may hold an inquest. These circumstances, of course, imply that there was no physician in attendance at all, or at such a late period, that he was not, up to the time of death, able from the symptoms to make a diagnosis of the case and explain the cause of death.

An exception would probably be made in the case of very old people, whose death there would be very good reason to believe was the result of senility.

If, however, the deceased was known to be ill or ailing previous to his death, especially if such illness was one of a serious character, and one from which death as a result would cause no surprise; and if the deceased at the time of his death was surrounded by members of his household, or by those who could not have held any but kindly feelings towards him in his extremity, and could not be suspected of having any motive to cause his death, and, particularly, if among these there was a physician who was treating him for his ailment, the case would be different.

It may be observed, however, that the mere presence and attendance of others, who may have come upon the scene when the deceased was *in articulo mortis* would not always be decisive. After-discovered circumstances might indicate suicide, poisoning, or some other unlawful cause of death.

If credible reports reached the coroner that, behind all indications of natural death in any particular case, there are suspicious circumstances, it would, of course, become his duty to investigate the matter at least by a preliminary investigation, and, if the suspicions should seem to be well founded, to hold an inquest. Suspicious circumstances, if reasonably well founded, would in any case of death, justify the coroner in holding an inquest.

It would undoubtedly be his duty to hold an inquest where the deceased is found, not in bed or in a residence or habitation, but in an out-house or building, or in a yard or field, or in the highway. If the deceased has been found in such places a suspicion might well arise that the deceased had died from unnatural causes.

In determining what his duty is in any particular case coming, or seeming to come, under this head, the coroner should carefully consider the circumstances of the case, and often also the character of the people who surrounded the deceased, or who were last in contact with him, and on whose conduct and character the holding of an inquest might cast an unpleasant imputation. He should try to obtain information not founded on vague and unreliable rumors; and, if such information brings the case within the principles above stated, he should proceed to hold an inquest.

In the case of Lancaster County *vs.* Mishler, 100 Penn. St., in which the right of the coroner to recover fees was disputed, it was decided that though the presumption is that the coroner has acted in good faith and on sufficient cause, yet in a suit against the county to recover his fees, this presumption is not conclusive, and that evidence is admissible to show that he acted in bad faith and knowingly, without sufficient cause or reason. In behalf of the county the offer

was made to prove "that at the time of his death the said Hahn (the deceased) was 78 years of age; that he had been sick, and attended by his regular physician for some days immediately preceding his death; that he died in his own house, surrounded by members of his family; that his death was a natural one, that there was nothing suspicious, sudden or extraordinary, and that all these facts were communicated to the coroner before he summoned his inquest." This offer was excluded by the court below, on the ground that the holding of an inquest is a judicial inquiry authorized by the laws of the State.

But the Supreme Court, as above stated, reversed this ruling, and held that the evidence should have been admitted. The Supreme Court said: "It is the duty of a coroner to hold an inquest *super visum corporis* where he has cause to suspect the deceased was feloniously destroyed, or where his death was caused by violence. Whenever he holds one the presumption is that he acted in good faith and on sufficient grounds. The question now presented is, whether in a suit by him for his services that presumption is conclusive against the county or may it be overthrown by evidence. The duty of a coroner to hold an inquest rests on sound reason, on that reason which is the life of the law. It is not a power to be exercised capriciously and arbitrarily against all reason. The object of an inquest is to seek information and obtain and secure evidence in case of death by violence or other undue means.

"If there be reasonable ground to suspect it was so caused, it becomes the duty of the coroner to act.

"If he has no grounds to suspect that the death was not a natural one, it is a perversion of the whole spirit of the law to compel the county to pay him for his services. Nay, more. If under the facts offered in evidence a coroner may hold an inquest, he may in his discretion, at the expense of the county, order a *post-mortem* examination, whereby those bound to the deceased by the nearest and most tender ties may have their feelings lacerated, in every case of natural death."

In case of death from accident, it is perhaps still more difficult to lay down a definite rule of conduct for the coroner. Such cases of death, being usually attended by horrible and extraordinary circumstances, are, no doubt, regarded by many as coming under the jurisdiction of the coroner, and it is probably true that in most of these cases coroners do proceed to hold an inquest. On the other hand, as the cause of death in cases of accident is often, if not generally, quite apparent, and as the reason for holding an inquest, if there is a reason, is often more or less obscure, it is to the holding of an inquest in these very cases that many object on the ground that it causes a needless expense, and harasses the feelings of the friends and relatives of the deceased.

In the case of Lancaster County *vs.* Dern, 2 Grant, 263, etc., the language of the Supreme Court is: "In this State the general understanding of his (the coroner's) duty is, that he is to inquire into the cause of all violent or extraordinary deaths."

From the language used in Crosby's case, 3 Pitts., 425, we may, perhaps, obtain a suggestion which will enable us to observe a distinction in cases of violent deaths from accident, and to determine with tolerable accuracy when the coroner has jurisdiction. In that case it is said: "An inquisition ought not to be held where the defendant (deceased?) came to his death by being caught in machinery which he himself was working, and no other person is suspected of contributing thereto."

It may be well at this point to state what is probably a fundamental principle in the law as to coroner's inquests, at least in cases other than those of suicide.

It is to determine, on grounds of public policy, whether any person has unlawfully contributed to the cause of death which has become the subject of inquiry, and has thereby made himself liable in a criminal or civil action.

An investigation by the coroner at the public expense, of cases of death, however extraordinary, from mere curiosity or for the purpose of advancing medical or surgical science will not be tolerated. The mere fact of death by accident, would not in every case give the coroner jurisdiction.

In Lancaster County *vs.* Dern, above referred to, the payment of the coroner's fees was resisted on the ground that the inquest was not necessary. The cause of death was the injury received in a collision of sleighs. The collision occurred on January 10, 1852, and the death on January 14.

The Court, after saying what has already been quoted from this case, proceeds as follows: "In this State the general understanding of his duty is, that he is to inquire into the cause of all violent or extraordinary deaths. It is frequently of great importance to the administration of justice, when the case becomes the subject of legal investigation, that death occurring by violence should be legally

inquired into by the coroner, and should he in a case of that kind neglect to do so, he would be justly censurable and might render himself obnoxious to the law for a neglect of duty. Now, in the case under consideration, the death of the person was not of an ordinary character, but one of violence, and, in our opinion, a case strictly within the supervision of the coroner; that it was his duty to ascertain, with as much precision as possible, the nature and cause of her death.

"It is contended that the death should not only be violent, but also sudden, and that both these circumstances must concur to give the coroner jurisdiction; that in as much as Catharine Lenocomer languished for several days after receiving the injury, therefore, although her death was violent, but not being sudden, the coroner had no legal right to hold the inquest. We cannot take this view of the law, for we are satisfied that, when the death occurs from any violence done to a person by another, although such violence may not terminate the life of the party suddenly, it is still the duty of the coroner to hold an inquest; for, otherwise some of the greatest benefit resulting from the office of coroner would be lost."

We conclude, therefore, that the coroner should hold an inquest in cases of death from accident where there were present others, or another, who, having participated in the work or operation from which accident occurred, may have contributed to that combination of circumstances which caused the accident, and as we have seen the death need not be sudden.

It is well known that such cases frequently become the subject of litigation in civil or criminal courts, and they are, therefore, proper subjects for investigation by the coroner. We should think that this is the feature which would give the coroner jurisdiction in almost all railroad accidents. We are all aware that most of these become the subject of litigation in a suit for damages.

If, however, it is clear that the cause of death was an accident, the causes of which were then and there set in motion, and that there was no one present who in any manner contributed thereto, it would be useless to hold an inquest, because in such a case there would be no probability that any one could be charged with having contributed to the casualty, and it would be of no interest to the public to have anything relating to such an accident officially determined.

There might, however, be exceptions to the rule just stated in reference to cases of accident where no one was present except the deceased. Such accident, though not directly contributed to by any one present, might have been caused by the previous neglect of some one in doing or omitting to do something, which neglect was the cause of accident. As where one leaves a hole or opening in the street or sidewalk uncovered which it was his duty to cover, and another should, without any contributory negligence, fall into such opening and receive injuries resulting in death.

Public interest or concern is certainly one important test which should determine the coroner's conduct. Where it appears that a life may have been sacrified by an act or an omission contrary to the duty which one owes to another, under the law, it becomes a matter of public concern and proper for investigation by the coroner.

In all cases of doubt there is one suggestion which it would be well for coroners, who mean to act according to the law, to heed; and that is, that they should carefully make a preliminary investigation of the most obvious facts, before proceeding to hold an official inquest.

W. B. Erdman, M.D., *Chairman.*
David Engelman, M.D.
J. Buzzard, M.D.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, February 8, 1888.

The President, J. Solis-Cohen, M.D., in the chair.

Dr. Mordecai Price read a paper on a

Case of Nephrectomy for Gunshot Wound.

Maggie McG., of Avondale, Chester County, Pennsylvania, aged 14 years, white, pale, anæmic girl, was accidentally shot on Wednesday, December 21, 1887, at nine o'clock in the morning, while handling a four-barreled Sharp's pistol, 30 calibre. She had the muzzle of the pistol turned toward the right side, and while attempting to raise the lock with the thumb of her left hand, the trigger slipped from her hold and fired the cartridge, which entered her body at the junction of the ninth rib with its cartilage. The ball passed directly through the left lobe of the liver, entered the upper third of the kidney, and passing through, lodged in the deep muscles of the back near the spine. When I first saw her, twenty-four hours after the accident, her condition was an exceedingly alarming one; pulse 150, temperature 103°. She had passed, soon after the accident, a large quantity of blood from the

bladder; but at the time of seeing her she was not passing blood from the bladder, showing that, if there was still hemorrhage, it was into the peritoneal cavity, and also that the bladder was not wounded, for the urine was normal.

Symptoms of peritonitis were well marked; abdomen considerably distended. We had no difficulty in coming to a conclusion as to what was best to be done. Dr. Charles Penrose and myself at once advised the removal of the kidney. This was concurred in by Dr. Hudders and Dr. Ewing, the attending physicians. The patient was etherized and opened. A large quantity of clotted blood was removed from the abdomen, the wound of the liver was examined, both entrance and exit. No hemorrhage was found coming from it. The abdominal incision was then enlarged, and the blood removed from the region of the right kidney, when it was plainly seen that the hemorrhage was from that organ. The kidney was examined and found to have a hole in its upper third, large enough for a finger to enter. I then made a button-hole opening through the peritoneum with scissors, introduced the finger and enlarged the opening by tearing, and without much difficulty enucleated the kidney from its bed. The ascending colon was pushed back or inward toward the spine, and the opening in the peritoneum, through which the kidney was removed, was made in such a manner that the vessels of the bowel were not disturbed. The ligaturing of the pedicle was exceedingly difficult, Dr. Penrose having to tie the ligature the full length of his hand in the peritoneal cavity. Two ligatures were applied, one through the pedicle, tying it in halves, the other a large, heavy ligature with one knot; then the kidney was cut away and the ligature tightened before making the second knot. The stump of the pedicle or button, as it is called, to keep the ligature from slipping, had a portion of kidney structure in it. There was complete irrigation. A glass drainage-tube was left in the kidney wound and the abdomen closed. The patient rallied nicely from the ether, and on the morning of the second day Epsom salt was given in large and repeated doses, but could not be retained. On the morning of the third day a second attempt was made to have her bowels moved. Rochelle salt was used, and was followed by two or three evacuations and the passage of flatus by the bowels, which gave great relief. Patient did uninterruptedly well, with temperature not over 102°, up to the time (eighth day) of the removal of the glass drainage-tube, when rubber drainage was substituted, and was left too long, producing quite a rise of temperature and fetid pus at the bottom of the tube, which was at once relieved by the attending physicians removing tube and cleaning drainage track.

On January 4, I was telegraphed for, patient's temperature having been up to 103° the previous night. Abscess was suspected, either in the liver or muscles of the back. I met Dr. Hudders and Dr. Ewing, her attending physicians, in consultation, and found no positive indication of abscess; the girl being in a moderately good condition at the time, with a slight tendency to diarrhœa; temperature 100.4°, pulse 100. She continued to do well until the 11th of January, when Dr. Ewing wrote me: "Some new trouble seems to be developing in our patient; her temperature is 103.2°; her liver is enlarged and tender; complains of pains in left side and shoulder." On the 12th, there was quite a gush of pus and bile from the drainage-tube opening—about two ounces. This at once relieved her of high temperature and quick pulse. She has had many changes in the last three weeks, with slight discharge of bile and pus from the drainage-tube; but has constantly, but very slowly, improved. Her physicians have given her every attention, and to them I am greatly indebted for the care they have given her; nothing but their interest in the case could compensate them for their labors. For the result in this case I am greatly indebted to Dr. Charles Penrose, for assistance rendered during the operation. Length of incision, six inches. Kidney removed for hemorrhage.

In opening the discussion, Dr. Ewing, of West Grove, said: I have nothing to add, except that the condition of the patient is better than Dr. Price states. To-day there was only a drachm of pus discharged. There is refreshing sleep; temperature is normal in the morning, though there is a slight evening rise; appetite is good; the bowels are regular. I feel that recovery is assured. This child was on the verge of death when the operation was done—the pulse was 150; temperature, 103°; the extremities were cold; the body covered with clammy respiration. Improvement was manifest at once. I am personally much indebted to Drs. Price and Penrose for this operation, and I attribute its success to the neatness and dispatch with which everything was done, which exhibited a high order of skill.

Dr. J. B. Roberts said: The case speaks for itself. While I cannot speak from expe-

rience, it has occurred to me, and the same suggestion has been made by others, that the difficulty of tying the stump so far down and behind the peritoneum, might be lessened by getting the kidney enucleated and then twisting it so as to apply torsion to all the renal vessels, veins as well as arteries. Afterward the ligature might be applied with more ease; and this, whether abdominal or lumbar incision be made, though in the absence of experience I judge that it would be easier to do this with a lumbar incision. I presume that there was no intestinal wound in this case, no mention having been made of any.

In connection with the operation by lumbar incision, I might refer to an error of my own which illustrates the mistakes our lack of familiarity with operations in this region may lead us into. The operation was undertaken for a supposed stone in the kidney; but as no stone was found, it resolved itself into an exploratory incision and acupuncture of the kidney. The ordinary lumbar incision had been made with care, and I had come upon the kidney with ease. It was suggested that I should enlarge the wound upward and explore the upper end. A few muscular fibres stretched across the upper angle of the wound, and these I divided by a small cut, when a rush of air into the pleural cavity informed me that I had cut a small hole in the diaphragm. The accident did no harm; it was easily remedied with a few sutures; and the dyspnœa that persisted for a few days was attributed by the patient to the tightness of the abdominal bandage. I was not sufficiently familiar with operations in this region to realize to what extent the posterior attachment of the diaphragm to the vertebræ dips down here, especially when I saw, as I did, the main mass of the diaphragm bulging down as a great sheet in front of the point where I made the additional incision.

The PRESIDENT said: How does Dr. Price account for the bile?

DR. PRICE said: I cannot say where the bile comes from, unless it comes from the liver. The wound in the liver is about two inches from the gall-bladder. The ball took a diagonal course and came out at the margin of the liver, and then entered the kidney. I did not know what the effect of twisting the pedicle would be. I could bring the edge of the kidney within an inch of the wound. I consider the abdominal incision the proper one. In this case there were several considerations in its favor. Hemorrhage had already taken place into the peritoneal cavity; it gave us the chance to examine for wounds of the liver and intestines. We found only wounds of the liver and kidney. The liver was not bleeding, and we had only the kidney to deal with. In view of the discharge of pus from the liver, I now believe that it would have been better to insert into the track of the bullet in the liver a small glass drainage tube—this of Bantock's, which is of about the same diameter as the ball—and drained it. If, as has been stated to me by Dr. Wood, there has been no case of recovery from bullet-wound of the liver, we are not going to make the prognosis any worse by draining, and I think we might make it better.

DR. C. B. PENROSE presented a specimen of

Dermoid Cyst of the Ovary,

which he had removed two days ago. The woman also had a uterus filled with many subperitoneal and interstitial fibroids, and a large blood cyst of the other ovary.

DR. PENROSE also reported a case of

Obstruction of the Bowel by cancerous Mass; Operation; With Formation of artificial Anus.

The operation was performed seven days ago. There had been complete obstruction of the bowel for twenty-eight days prior to operation. Fecal vomiting occurred two days before operation. At time of operation there was immense abdominal distention, a temperature of 101°, and pulse of 150. An abdominal incision four inches in length was made, revealing complete occlusion of the descending colon by a cancerous mass twelve inches long, involving also the meso-colon.

Resection was made of the gut and meso-colon, and all indurated tissues were removed. The two ends of the divided gut were brought together laterally and united to each other, and the long axis of the abdominal incision, with continued suture, so as to make an artificial anus. A bucketful of fluid feces was discharged immediately after the operation. Relief was immediate; quiet sleep lasted for thirty-six hours. To-day the abdomen is flat; the pulse is 80 to 90; temperature, 99°; there is no pain; the tongue is clean; appetite good, and the patient doing remarkably well.

BALTIMORE CLINICAL SOCIETY.

Stated Meeting, Feb. 3, 1888.

DR. HIRAM WOODS read a paper on

Three Cases of Hallucinations due to the Administration of Sodium Salicylate.

The power of sodium salicylate to relieve the pain and shorten the duration of some of the intra-ocular inflammations is now, I think,

generally recognized. Iritis and choroiditis are the inflammations specially amenable to this treatment. Nor is its good action limited, as might be supposed, to those cases having a rheumatic origin. Iritis, clearly due to syphilis, without the least suspicion of rheumatism, I have frequently seen quickly relieved by the salicylates. Mercury will cure in time, of course; but the salicylates seem to have the power of aborting the attack. To accomplish this result, the system must be speedily brought under the influence of the drug, and this requires large doses. This fact gives us a clue to its mode of action. Large doses of the salicylates have the effect of weakening the heart's action, and reducing the blood pressure. These results are brought about by the combined depression of the contractile force of the cardiac muscle and of the vaso-motor centre. The latter produces not only a fall in blood-pressure, but prevents a rise in the pressure when the sensory nerves are irritated (Brunton, Materia Medica). These facts place sodium salicylate —if given in large doses—among the antiphlogistics, with aconite, veratrum, large doses of quinia, etc. Still, I can hardly believe that all the antiphlogistic effects of the salicylates are due to their depressant action on the circulation. Other drugs which lower blood-pressure—for instance, the bromides and those already mentioned—do not sensibly relieve the pain nor effect the course of iritis. There seems to be a selective action which we little understand. The large doses required often produce effects which are not only disagreeable, but may, in exceptional cases, become dangerous. Nausea, tinnitus aurium, deafness, fulness in the frontal region of the head, wakefulness, are the symptoms commonly met with. The amount which will produce these physiological effects usually stops the inflammation, or by its failure, induces us to use other means. More rarely, violent purging, involuntary evacuations, great dyspnœa and collapse are observed (Bartholow). Prof. Chisolm, of this city, reported two or three years ago a case of purging and involuntary evacuations occurring in a patient, who took, through a mistake of the druggist, 192 grain instead of 24. There were, in addition, marked depression and weakness, but the patient fully recovered in two days. The force of the drug is sometimes expended wholly upon the nervous system. Such extreme effects as complete deafness, ptosis, strabismus are mentioned in our text-books as having been occasionally observed. Bartholow mentions a case of amaurosis due to the administration of 125 grains. There was no retinal lesion. Delirium and visual hallucinations are nervous phenomena more commonly observed than those just mentioned. Brunton says: "Salicylate of sodium in some persons tends to cause most disagreeable visions, whenever the eyes are shut, and I have seen it have this effect even in such a small dose as five grains" (Materia Medica). According to Bartholow, it is specially apt to produce delirium in drunkards. In the *British Medical Journal* of January 29, 1881, Dr. Bastian presents a series of five cases of delirium and visual hallucinations following the use of sodium salicylate in acute rheumatism. One case was that of an old toper, and the character of the delirium was similar to that of delirium tremens. In another the rheumatic poison seemed to be specially virulent, and the delirium was more like that sometimes observed in acute rheumatic fever, and due only to the rheumatic influence. Dr. Bastian concludes that if the patient's condition is such as to predispose to delirium, the salicylate will probably precipitate the attack, which, in its characteristics will resemble the delirium occurring in the predisposing disease. Cases, however, are here and there recorded in which, like those immediately to follow, there was no pyrexia to produce the trouble, nor any influence which could be held responsible except the salicylate.

Case I.—Mr. J. S., aged 43, occupation journalist, consulted me in April, 1886. He had had iritis in the right eye for four days. The iris was muddy, the pupil contracted, the periphery of the iris bulged forward, and there was pus in the anterior chamber. Pain was intense, not only in the eye, but in the temple. There was no syphilis, but an attack of rheumatism three months previous to his visit to my office, seemed to offer an explanation for his iritis. There was, so far as I could make out, no organic heart trouble. He gave a distinct history of phthisis in the family, and while I could not find a cavity in either lung when I examined him, there was dulness over the apices of both lungs, there was considerable emaciation, and he had a cough which was sometimes very troublesome. I have not seen him since I discharged him in the spring of 1886, after his iritis had gotten well; but he wrote me, from his home in Baltimore county, during the past winter that he had been obliged to give up nearly all his work, that his cough was incessant, and he was growing weaker. Undoubtedly he has fallen a victim to phthisis. His habits were temperate. He said he usually took a glass of sherry with his dinner,

and, sometimes, a little whiskey at bed time. I applied a compress bandage to his eye, ordered the instillation of a 4 gr. atropia solution, and prescribed for him 20 grs. salicylate of sodium every four hours. When he called at my office the next day, I was engaged, and he sat in the waiting-room about half an hour. After I had examined his eye, finding it greatly improved, he asked: "Doctor, is there a big colored woman with a child on her lap sitting on the sofa in the other room?" I told him I did not think there was, but to satisfy him, I looked and found no one there. On learning this, he said: "I wasn't *sure* of it. I didn't see her until I had been in the room a little while, and then she wasn't clear enough to make me sure." On questioning him, I found he had, to settle the question in his own mind, gone up to the sofa, and tried to touch the supposed woman, and found his hand came down upon the sofa. He then told me that he had taken four of the powders between 10 A.M., and 10 P.M., the day before, making 80 grains in all. He retired about 10 o'clock, and did not take a stimulant that night. After being in bed a little while he noticed his ears buzzing. He could not sleep, and soon thought he was having a dispute with his son. He sat up in bed, made up his mind that it was all imagination, laid down again, and talked away at his son as much as ever, so much so that his wife asked him to stop talking. After while the delirium changed and he thought he was at the telephone in his office, and couldn't speak above a whisper. He got out of bed two or three times during the night to answer a supposed telephone call. In the morning, while coming to town in the cars, he was troubled by seeing a black cat on his knee. He could convince himself that these things were all hallucinations; but no sooner would he do this than they would all come trooping back as real as ever. When standing alone he suffered from giddiness. His pulse was about 80, temperature normal. I had him pass his urine in my office and found it free from albumin. The salicylate was stopped. He slept very little that night, but the next day seemed completely himself. The iritis was afterwards treated with potassium iodide and the alkalis.

The other two cases occurred in the private practice of Prof. Chisolm, who has kindly written out for me the following notes:

Case II.—L. G., aged 50, of temperate habits, has been for ten years troubled with repeated attacks of specific iritis. Each attack runs its tedious course of six weeks or two months under the orthodox treatment of iodide of potash and mercury, with the local use of atropia and an occasional application of leeches to the temples. Four years since the treatment was changed to the salicylate of sodium in 25 grain doses given four times a day. The drug alleviates very promptly the inflammatory attacks, and enables him often to get out in a fortnight—a marked shortening of the paroxysm. In his case the remedy is not without its detractions. It does not disturb very materially his digestion, but when continued for some days produces very curious psychological effects. By the fourth day of taking, particles of dust become conspicuous against white surfaces and pollute the water which he drinks. The particles covering his white bed-spread grow in size into green flies and some of these develop into green frogs with a few green snakes. They are not stationary but are in constant motion. He knows them to be an illusion, but they look very real notwithstanding. If the medicine is stopped at this stage of the mental disturbance, in twenty-four hours they are all removed, disappearing in the transition forms in which they introduced themselves. Should it be needful to continue the large doses of the salicylate, figures of men, not always with the most pleasant countenances appear on the scene. At one of my morning visits, my patient reported his night's sleep as much disturbed by the intrusion of three men into his chamber. In waking, by the dim light of the turned down gas, he saw three men inspecting his box of valuable papers, which they for convenience had transfered to a side table. He reasoned with himself that no one could get into his house and that his body servant was in the contiguous room. He could shut out the vision by closing his eyes. At my visit he was sitting facing an open door leading into the next chamber. After describing his visions of the previous night, he said: "Now I know perfectly well that there is no one in that room, pointing to the door, and yet there stands in a threatening attitude a big man with an ugly club. I can shut him out by shutting my eyes, but there he is all the same."

On another occasion, after using the salicylate for some days, with the recurrence of motes, then flies, frogs and snakes, always green ones, I found him at midday sitting in the dining-room. As soon as I had examined his eyes and found that the injection had nearly disappeared, he said that he was very glad of it, and could now stop the sodium, because the hallucinations were becoming annoying. Just before I had

arrived, a mouse had come out from under the grate. After playing about on the rug, it commenced to puff up, and became a cat. The inflation continued, the animal becoming larger, until it assumed the appearance of a tiger, upon mischief bent. When the animal crouched with the intent of springing toward him, he asked his mother, who was reading the morning paper at the window, to come toward the fireplace. In doing so, she got between himself and the threatening animal, and the illusion vanished. During these conditions of mental excitement, the reasoning powers were never disturbed, nor did the conversation at any time indicate otherwise than a clear head. In this case the psychological influences seemed always to run in the same channel. These experiences had occurred to him on several occasions, at many months of interval, and always in a regular order. After three or four days taking large doses of the salicylate, he would mention to me: "Doctor, I saw the little pieces of stick in my basin this morning; the flies will come before the day is out."

Case III.—Miss S., aged 50, had been operated upon for double acute glaucoma. Vision had been reduced to light-perception before operation, and was so perfectly restored that she could use her eyes for hours daily in confined literary pursuits. Four years after the iridectomy, her left eye was attacked with a sharp inflammatory attack, which she conceived to be a return of her glaucomatous trouble. I saw her after three days of suffering, and found an acute attack of iritis, with some pus in the anterior chamber, a heavy rim of injection around the cornea, a very painful eye, with very dull vision. The salicylate of sodium was given in twenty-five grain doses, four times a day. By the second morning all congestion had disappeared from the eye. The media had cleared up in a wonderful manner, and vision had returned. She stated that she had had a most horrible night of hallucinations of most disagreeable forms. She was very glad to know and feel that the eye was so very much better. She had made up her mind, from the horrors of the preceding night, that she could not take another dose of the medicine, even if the safety of her eye depended upon it.

In my own case and the last of Prof. Chisolm's, the delirium came on during the first ten hours of the administration of the drug. In the *Practitioner* for May, 1882, Dr. C. S. Coulston publishes an interesting and exhaustive thesis on the use of the salicylates in rheumatism. Speaking of this delirium, he says that it usually comes on within the first eight hours, and is due to overwhelming the nervous system with large doses before tolerance is established, which can be readily done. If tinnitus aurium appears, the salicylate, Dr. Coulston thinks, should be discontinued until the tinnitus has gone. Then the salicylate can be given with freedom. Each of the five cases reported in the *British Medical Journal* by Dr. Bastian, afterwards took the medicine without trouble. In the extremely interesting case (the first narrated by Prof. Chisolm) the medicine seems to be well borne for three days, and then the delirium comes. Tolerance is not established. This case also opposes the remark of Brunton's that the hallucinations only appear when the eyes are closed. In each of these cases there was full knowledge that the objects seen *were hallucinations*, but they could not be permanently driven away. The patients were, on this account, not greatly terrified. Dr. Coulston states that the hallucinations are usually of a harmless, non-terrifying character. One of his patients insisted that a bundle of rags in the corner was the baby of an intimate friend, and that he had to take care of it. Occasionally, however, the delirium takes the form of mania, and the patient is violent.

In those diseases which sometimes of themselves cause delirium, the question of diagnosis becomes an interesting one. Dr. Coulston shows that the salicylic delirium is to be distinguished from that due to the rheumatic influence by the absence of fever and lessening of the joint pains at the time the delirium occurs. This was so with his cases, and with those reported by Dr. Bastian. The latter gentleman quotes the observation of Simon that delirium in rheumatism means involvement of the heart, and this may throw doubt on the influence of the salicylate in causing the hallucinations. In three of Dr. Bastian's cases there was no heart complication at all. From the delirium of drunkards (*delirium tremens*), it is to be diagnosticated by "the absence of tremulousness in the hand or tongue."

The manner of the production of the delirium is also an interesting question. As some of the cases also showed albuminuria, it was supposed that acute nephritis had resulted from the use of the salicylate, and that uræmia had caused the delirium. Subsequent cases have disproved this. In only one of Dr. Bastian's cases was there albuminuria. Dr. Ackland, quoted by Coulston, "thinks that uræmia, due to the great dimi-

nution of the amount of urea excreted by patients taking salicylates, may be an important factor in the production of the delirium. Dr. Bastian's opinion—that it precipitates an attack of delirium impending from some other disease—has already been alluded to. By others the delirium has been supposed to be due to impurities in the salicylate, and it is asserted that the *pure* salicylate never produces delirium." Dr. Coulston concludes his study of this branch of his subject with the remark: "The direct action of the salicylates on the nervous system is sufficient to account for the delirium, apart from either albuminuria, uræmia, or a rheumatic complication, though * * * * these would be predisposing causes."

Foreign Correspondence.

LETTER FROM VIENNA.

The feature of work in this city so attractive to the American student, is its purely clinical character and the large field for practical work and manipulation under teachers renowned for their scholarly methods. Increased facilities have more than offset the restrictions placed upon the management of the General Hospital by the Government, in favor of the Austrian and Hungarian students. In many popular courses a certain number of places are reserved for the native students, and the same applies to all of the summer courses.

The clinic of Prof. Nothnagel, formerly of Jena, is very popular with Austrian and Hungarian students, and hence it is difficult to obtain satisfactory places in his amphitheatre. He is a thorough scholar, conservative to a safe degree, an admirable lecturer and an esteemed teacher; and his course of clinical demonstrations on diseases of the chest is very complete. The great prevalence and variety of tuberculosis in this city furnishes an abundance of clinical material, and permits systematic demonstrations in all stages and forms of this disease. Nothnagel depends upon the presence of the bacillus tuberculosis in the sputum in making his diagnosis. At a recent lecture he emphasized this point, and urged the necessity of familiarity with methods of staining, and systematic search for the bacillus in the sputum of all cases of so-called catarrh of the apex. At the same time he acknowledged that in the incipient stages one may be baffled in the search, but generally, he says, because of imperfect methods; since he believes that the bacillus tuberculosis is present in the products of disintegration of all tubercular formations. His imitations and illustrations of the normal and pathological sounds elicited by physical diagnosis are very accurate and graphic, and his methods in general demonstrate that the progress of internal medicine is not entirely in the attractive fields of pathology opened up by modern study of bacteriology and chemistry.

His treatment of croupous pneumonia is decidedly expectant. He resorts to antipyretics only exceptionally, and in many cases in all stages before the class, I have not seen the use of any chest applications whatever. He recently considered a rare form of anæmia, occuring in Egypt, where tape-worm is very prevalent and its effects are very pronounced. In addition to the usual expression of malnutrition, bowel hemorrhages occur, and the patient is brought very low. Prof. Nothnagel inclines to the theory that some chemical product of the worm has a direct depressing effect on the hæmato-poietic system, thus producing extreme anæmia. The danger in such cases lies in the risk of administering efficient doses of the tæniafuge, and yet the anæmia obstinately resists treatment until the cause has been removed.

Prof. Schrötter, or rather his assistant, Docent Karis, has had two operations of tracheotomy for obstruction of the trachea before the class. The first was one of traumatic hemorrhage, and the patient was with much difficulty resuscitated from the combined effect of the hemorrhage and asphyxia. The second operation was for the removal of large polypoid growths below the vocal cords in a little girl. Both cases are doing well. Professor Schrötter exhibited a case illustrating the beneficial effect of tracheotomy in laryngeal, and even pulmonary tuberculosis. The patient was a woman, over 30 years old, who, before the operation, had distinct evidences of the involvement of the larynx, with cavities in the apex of the lung. She began to improve after tracheotomy, and gained thirty or forty pounds in weight, with apparent cessation of the tubercular manifestations, after a lapse of now eighteen months.

Privat-docent Chiari recently exhibited a case of leprosy of the larynx from the wards of Prof. Kaposi. The man is a Greek, and has been here for some time, enjoying apparently unrestrained freedom of the hospital precincts.

Prof. Störk is rather under a cloud in professional circles, after his deliberate attack on Sir Morell Mackenzie, and doubtless he himself feels the reaction the more forcibly

since the recent favorable turn of affairs in the case of the Crown Prince of Germany. A most amusing dispatch was recently published in the leading Vienna paper. It was to the effect that Professor Virchow had reversed his decision as to the nature of the Crown Prince's disease, on the ground that what he had taken for soft cancer cells was merely the deposit of small particles from a dish of preserved fruit, just eaten by his Highness.

Professor Joseph Gruber conducts most satisfactory ear clinics. He has great confidence in operative measures in general, and is very skilful in manipulations. The use of the catheter is almost the rule in middle-ear inflation, and bougies are very frequently used in Eustachian tube disease. He treats inveterate tinnitus aurium by incisions of the drum membrane, releasing the long process of the malleus, and altering the tension in the internal ear. He has tried injections of hydrate of chloral, but with indifferent result. A new collodion-like substance, used in photography, offers an excellent medium for closing old perforations. It is called photoxyline, and is applied direct, with but slight pain, with a camel's hair brush.

There has been a series of unfortunate results in cases of mastoid disease in the wards of Prof. Politzer. None of them admitted of operation. The autopsy of one, a young girl, revealed an abscess, which had burrowed down along the course of the sterno-mastoid muscle into the anterior mediastinal space.

The death of Dr. Craig, of Middletown, Conn., in December last, made a deep impression on all of his colleagues. He had suffered from middle ear disease for some time, and it culminated in involvement of the venous sinuses, with a fatal result in a short time. Dr. Craig was graduated from the Harvard Medical School in 1883, and came abroad in November, 1887, to pursue his studies. His thorough education was acquired by his own energy and ambition, and was most creditable to him. His disease was most intractable and baffled the skill of the best specialists in Europe.

Prof. E. Fuchs, successor to Prof. Arlt, is carrying on a most successful clinic. The size of the ambulatorium (number of walking patients) is an indication of the popularity of the clinic, and there are between one hundred and one hundred and twenty-five receiving treatment daily. In his cataract operations the modified linear incision is used exclusively; and in ordinary cases the capsular forceps are substituted for the kooh in removal of the capsule. A few weeks ago Prof. Fuchs extracted a small piece of iron from the vitreous chamber with remarkable success. The patient was a young boy, and nearly a week had elapsed since the accident before the operation was undertaken. Several distinguished visitors were in attendance, and among them Karl Theodor, brother of the Empress, who has interested himself not a little in eye surgery. The foreign body lay not far from the posterior wall of the eye. An incision of sufficient size to admit the pole of the electro-magnet was made in the sclerotic, and on the second introduction the piece of iron was found clinging to the magnet. The case went on to a most favorable recovery. Prof. Fuchs is a clever operator, and very successful in his general management of the wards. His antiseptic precautions are extreme. All instruments used in operations on the eye are first heated in boiling water for some time. During the operation corrosive sublimate solution (1 to 5000) is used, and the after dressing is begun with pulverized iodoform and gauze.

Prof. L. Mauthner recently announced before his class the discovery of a new local anæsthetic by Lewin, of Berlin. This alkaloid, erythrophlœine, can only be used in very weak solutions; one to one thousand has been found quite efficient. The anæsthesia may last one to two days, or more. There is but slight or no effect on the pupil except in strong solution, and then it is a myotic. Its penetrating power is much greater than that of cocaine, and it will doubtless be useful even in enucleations of the eye, and in other fields in which cocaine has failed. It is a heart depressant in strong solutions, but there is no constitutional effect produced by the weaker solution. The anæsthesia comes on somewhat slower than that of cocaine. It was a remarkable coincidence that even during these remarks, Dr. Koller, the student who announced to the world the remarkable properties of cocaine, entered the room and was presented by the professor. Dr. Koller is still carrying on his studies here as assistant in different departments, preparatory, I have heard, to coming to America.

The Hygienic Congress of September, was a decided success. Vienna is indeed most hospitable, and all joined the local medical body in entertaining the unprecedented assembly of representative scientists. It can scarcely be said that they have reformed Vienna in her many unhygienic features, but all civilized lands must soon feel the influence, to a greater or less degree, of the published proceedings and individual studies

of this assembly of scientists. It was curious, however, to hear hygienists discussing questions relative to the welfare of all people, in an atmosphere loaded with carbonic acid.

The larger part of the nearly three thousand members in attendance came from Austria and Hungary, but France, Germany, Russia and the Scandinavian countries, sent large representations. England was represented by a very distinguished body, including Sir Spencer Wells, Francis Galton, Prof. Frankland, and others equally famous for their labors in sanitary science. The part taken in the discussion by the English delegates was very important, and they succeeded in having London chosen as the place of next meeting, for 1891.

Prof. Pettenkoffer remarked in his opening address, that the study of hygiene, as a science, is growing beyond the comprehension of the medical profession, and unless medical instruction is modified to include more of this instruction, it will soon stand entirely free from their fostering care, as an independent science. Our own country is behind the other great countries in labors in this field, and only by systematic energy can a better position be gained.

THOS. HUBBARD, M.D.

February 3, 1888.

PERISCOPE.

The Diagnosis and operative Treatment of Intestinal Obstruction.

Mr. Henry E. Clark, in a paper read before the Glasgow Medical Society, and published in the *Glasgow Medical Journal*, January, 1888, discusses the always interesting subject of intestinal obstruction. At the outset of his paper, he alluded to the difficulties surrounding the study of this subject, but looked hopefully for progress in the near future, both as regards diagnosis and treatment, in consequence of cases of intestinal obstruction now coming under the hands of the surgeon instead of the physician. While deprecating hurried and inconsiderate resort to operation, he showed that, for a large number of cases, this gave the only chance of recovery; and pointed out that, even when unsuccessful, abdominal section gave valuable information, which, if accumulated, would give a sounder basis to our knowledge, and lead to the saving of many lives. He next passed in rapid review the several forms of intestinal obstruction, and stated what he believed to be the essential diagnostic points; he illustrated his remarks by short histories of some of the cases which had passed through his hands during the past few years.

In summing up his operations, he laid down the following propositions:

1. Much evil is done in cases of intestinal obstruction by the injudicious use of purgatives. By their use the incomplete obstruction becomes complete, and the chronic obstruction becomes acute.

2. The most important question to decide is whether the obstruction is complete or incomplete. If flatus is passed *per anum* the obstruction is incomplete, and we are justified in waiting on in hope, and doing our best to avoid operation.

3. Opium is still our mainstay, and should be carefully and persistently used. Next to opium, nothing is so valuable as belladonna, both administered by the mouth, and applied externally to the abdominal wall. The diet should consist of milk, alone, or mixed with soda water or lime water.

4. The treatment by shaking the patient, as recommended in Erichsen's *Surgery*, last edition, being simple and safe, might be tried, and no doubt in some few cases would be found successful.

5. If opium, belladonna, enemata, and shaking are found to give no permanent relief —the obstruction being complete or becoming more complete, pain increasing, pulse not improving, abdominal distension getting greater, peristalsis visible, vomiting a marked feature—counsel operation. Undoubtedly in such cases abdominal section by mesial incision offers the best chance of relief.

6. Diagnosis of the exact site of the obstruction is generally difficult. Early vomiting generally means that the obstruction is high up. Much may be learned by careful percussion of the abdomen, especially along the line of the colon.

7. In cancer of the bowel, where there are signs of obstruction in the upper part of the pelvis, we should give our patients relief from the immediate symptoms and an extension of life by colotomy.

8. In the earliest condition of intussusception, inflation, by means of bellows or special force pump, offers a chance which should not be neglected; but in a latter stage it is accompanied by risks, both real and great, so as to render its use inadmissible.

Perforation of an Eye-ball with the Knot of a Whip.

A remarkable, if not unique, accident occurred in London recently to one of the staff, at the Paris Hippodrome. Whilst some ponies were being put through their usual training, an attendant, who was standing just outside the ring, suddenly felt a severe

blow upon his left eye, which, at the time, he believed to be due to a small stone. The next day the patient, on the advice of Dr. Towers Smith, the medical officer of the company, was removed to the West London Hospital, and, on the following afternoon, symptoms of panophthalmitis having commenced, enucleation was performed by Mr. H. Percy Dunn, assistant ophthalmic surgeon. On examination of the globe after removal, a large knot from the lash of the whip which had been used in the ring was found lying imbedded in the vitreous, the knot having passed into the eye through a jagged perforation at the corneo-scleral junction just below the horizontal meridian on the inner side. The interest of the case rests in the fact that, from accurate measurements which have since been made of the whip, the lash, and the *locale*, the man must have been distant from the end of the lash at least six feet when the whip was cracked; and the only explanation of the occurrence, which seem to be possible, is, that the knot was suddenly detached from the lash, and, with the momentum it had acquired from the cracking of the whip, penetrated the tunics of the globe, and caused the loss of the eye. —*Med. Press and Circular*, Dec. 14, 1887.

Examination of Sea-Air for Bacteria.

In the *Zeitschrift für Hygiene*, I. S., 421, Fischer has a paper upon the results of his examination of sea-air for bacteria in a trip which he made to the West Indies. In these examinations he used Hesse's method. He found that while the quantity of germs was considerable near the land, it was slight at a greater distance from the land (over ninety miles). But if the wind was from the sea, the air was free from germs at even a short distance from the land, showing that the direction of the wind has more to do with the quantity of germs in sea-air than simple distance from the shore. With reference to the statement that exceptionally at a very great distance from land (according to Darwin, about 1000 miles from the continent), a rain of dust may occur, the experiences of Fischer possess validity only for ordinary conditions. As regards the kind of micro-organisms found in the air, the moulds preponderate in comparison with the yeast fungi and the bacteria.

Finally, he investigated the sea-air by means of nutritive gelatine spread upon exposed plates. In these experiments contamination of the plates often occurred through scattering of the sea-water. In those which escaped this, subsequent test-tube investigation established the fact that the sea-air at a certain distance from the land is free from germs.—*Centralblatt f. d. Med. Wissensch.*, November 5, 1887.

Circulation of Blood in the Brain.

This subject has been studied anew by Wagner and Gaertner (*Wiener med. Blätter.*, 1887, No. 16) by exposing and opening the posterior facial vein, and measuring the amount of blood escaping in a given space of time. Among other problems, the influence of certain drugs was studied. It was found that morphia had little influence on the rapidity of the flow. Chloroform caused an enormous increase of the flow, as much as five times the original rapidity, although in a late stage of the narcosis the blood-pressure fell notably. With the disappearance of narcosis, the rapidity decreased. Amyl nitrite had a similar, though less intense, effect. Irritation of peripheral sensory nerves caused hyperæmia, never anæmia. —*Centralblatt für Chirurgie*, Nov. 12, 1887.

Local and intestinal Antisepsis in the Treatment of Furuncles.

P. LeGendre reports to *Le Concours Médical*, January 28, 1888, that he has tried the method of treatment, which has recently been recommended by Prof. Bouchard. A patient applied to him for treatment for a very large boil on his neck, the core of which had begun to be discharged. In the neighborhood of this boil another began to point, but it was still hard. The patient was much alarmed, because, two years before, he had suffered from an eruption of more than fifty boils, which for three months had embittered his existence. LeGendre protected the affected parts with an antiseptic plaster, which was to be changed twice a day, and directed the patient at these times to bathe the surface with a hot solution of corrosive sublimate, one part in one thousand. As there were undoubted signs of digestive derangement, he ordered, in addition, the following prescription as an intestinal antiseptic:

Beta naphthol,
Salicylate of bismuth,
Carbonate of magnesia, of each, 4½ grs.
M.—To make one powder.

This powder was to be taken every fourth hour. In eight hours the patient returned in excellent spirits; the first furuncle had dried up, the second was aborted, and there was no sign of the appearance of any others. The treatment was kept up with strictness for a week, and then stopped.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE AMERICAN MEDICAL ASSOCIATION.

The next meeting of the American Medical Association will be held in Cincinnati from May 8 to May 11. The indications are that the meeting will be very large, and the members of the medical profession in Cincinnati have already made arrangements which insure the fact that, so far as hospitality can effect this, the meeting will be one of great pleasure. The arrangements provide accommodations for more than 4000 delegates, as the hall in which the general meetings are to be held will seat 3600 persons on the main floor, and 600 more on the stage, besides 2500 in the galleries. There are in the building ten rooms available for the meetings of sections. Thus it will be seen that Cincinnati promises accommodations for the mere size of the Association such as could be provided in few cities of the United States.

It need hardly be said that the citizens of Cincinnati have made arrangements for the entertainment and amusement of their guests, which give promise that this feature of the meeting will in no respect fall behind the experience of past years. In fact, there is every reason to believe that, so far as Cincinnati can bring it about, we shall see a most happy meeting of the Association at that city in May.

So far as the Association itself is concerned there are satisfactory indications that the coming meeting will be one of the most interesting and important which has been held for a long time. We believe that unusually full and able delegations will be present from all sections of the country, and that all will be animated by a sincere desire that the Association shall enter upon an era of renewed prosperity, and serve better than ever to knit together the hearts as well as the hands of the medical profession in America.

FREE TRADE IN MEDICAL AND SURGICAL INSTRUMENTS.

At the annual meeting of the Georgia Medical Society, held January 3, 1888, a resolution was adopted requesting the co-operation of the medical journals of the country in an effort to secure the removal of the duty now imposed by the United States Government upon medical and surgical instruments and appliances. The Corresponding Secretary, in communicating this resolution to us gives some reasons, which we publish elsewhere, why the course recommended by the Georgia Medical Society should be adopted.

We heartily sympathize with the object of this society, and wish that the manufacture of surgical and medical instruments and appliances could be so regulated that medical men should be able to secure good articles within reasonable time, at reasonable rates. And we believe that, however one may stand on the matter of free trade or protection in general, it is not inconsistent to favor free trade in surgical appliances and instruments; because in this case we are not dealing with an interest which needs fostering, but with an evil which calls for repression. The fact is, that instrument-makers, as a class, come very far from fulfilling what may be reasonably expected of them. And it might not be a bad thing to have them kept in order by foreign competition.

On the other hand, our readers need not suppose that removal of the duty on surgical instruments will bring a millenium, or that the cheap instruments of European make will always prove to be better than more costly instruments made here. There will be plenty of poor stuff foisted upon the medical men of America if the duties are removed, and the American instrument-makers will have a sad satisfaction in seeing imperfect instruments preferred to their own reliable ones, simply because the former come from Europe. So this plan is one not wholly free from disadvantages. And we would not endorse it—as we do—if we did not believe that the manufacturers of good instruments in this country would not be injured by the removal of the duties on imported instruments, and that it would be a good thing for everybody to have the manufacturers of poor instruments killed off. Finally, we venture a suggestion to the Georgia Medical Society: If it wants to have this thing done, it will have to make a business of it, and not suppose that one circular to the medical journals will accomplish it. We will help the society as we have opportunity; unless, on more mature thought, we doubt the advisability or practicability of what they wish.

THE NEED FOR PUBLIC ANALYSTS.

In a recent number of the *Westminster Review*, there is an article which calls attention in strong language to the duty of the State to protect its citizens against the unlawful adulteration of articles of food. There are differences of opinion in regard to the wholesome or unwholesome character of various substances introduced into certain articles of food, in order that the demand for cheap goods, which becomes every day more insistent, may be satisfied without offending against the equally insistent demand for substances bearing well-known names. Thus, oleomargarine is added to what is known as butter, and it is asserted that the addition puts the price of butter within the means of those who otherwise could not afford it, without detracting from its wholesomeness and palatableness. This assertion we think to be true. We would also agree that the use of glucose, for sugar, in the manufacturing of candy does not affect its wholesomeness in the least; and we have no hesitation in saying that we believe the dangers of the adulteration of articles of food are often exaggerated. One may concede this much to those who, with an appearance of reason, say: "The people will have what is called butter, or candy, or lard, or anything else, at a price for which none of them can be produced; and we give them what satisfies them and does no harm." But, this concession does not waive the right which the people have, to know what they are buying and to choose deliberately whether they will have it, or not. It may be true that few adulterations of articles of food do the slightest harm; but the people have a right to pass upon the question for themselves and with their eyes open, and not have it decided for them by those who might be human enough to be influenced by the commercial interest they have in believing that the adulterations which they make are innocent. For this reason, and also because a certain number—it may be a small one—of adulterations, such as those of milk and those which are made to secure certain popular colors, as in coffee, pickles, candies, cakes, and so forth, are far from innocent, we believe, with the writer in the *Westminster Review*, and with many sanitarians, that the State should take up the duty of securing for its citizens protection against adulterations which are carried on surreptitiously. The best way which has been suggested for the discharge of this duty consists in the appointment of public analysts, to be paid by the Government, who shall regularly analyze goods bought in open market, and also—still at the cost of the State—samples furnished them by any citizen who has reasonable ground for suspecting that they are adulterated. Certain precautions ought to be taken to prevent a misuse of the privilege of demanding such investigations; so that they should not be made subservient to foolish suspicion or to trade jealousy. These precautions, we think, it would not be hard to arrange; while the knowledge that

adulterated wares might be detected, either by the regular operation of the work of analysis or by a special analysis demanded by a suspicious customer, would probably restrain very materially those whose consciences would not prevent them from practicing dangerous adulterations of articles of food and drink.

For the securing and carrying out of a law such as we have indicated, none ought to be more ready than the large and worthy class which holds that lard is better and cheaper if made with cotton-seed oil, or that which thinks that oleomargarine is preferable to butter. Those who think that water or chalk improves milk, or that lead chromate is a good thing to put in cakes, or that poisonous coloring matters do no harm to candy, will hardly favor the appointment of public analysts. There is a homely old saw which says:

> "Rogue never felt the halter draw
> With good opinion of the law."

But we believe that all who respect honesty and fair dealing, will agree that public analysts, with large discretionary powers, ought to be a part of the sanitary machinery of every civilized land.

LOCAL REFRIGERATION WITH CHLORIDE OF METHYL — STYPAGE.

The use of various agents for the production of cold as a local condition for the purpose of lessening pain or annulling sensibility is no new thing. No doubt the human race was in its infancy when it was first discovered that cold water exercised a soothing influence upon many painful states. But the last forty years has witnessed a development of this knowledge, until the use of cold water as a local anodyne, or anæsthetic, is one of the recognized procedures of medical and surgical therapeusis. From cold water physicians have proceeded to the use of ice, of ice and salt; then to that of evaporating ether, after ether was discovered; and, after the invention of the atomizer, a variety of substances have been used to abstract heat by their rapid passage from a liquid to a gaseous state. For some time the chloride of methyl has been regarded as the most reliable agent of this class, and since it was condensed into a liquid form by Bérthelot it has become also one of the most convenient. It can also be obtained now at a comparatively low price from the by-products of distilleries.

A number of attempts have been made to render the method of using it more simple than it was in 1882, when Dr. Lailler, of Paris, constructed a peculiar receptacle for holding it, and M. Ledentu used this apparatus to produce local anæsthesia in a number of minor operations at the Hospital Saint Louis, in Paris.

The latest worker in this field is M. Charles Bailly, of Chambly, who has devised a plan of securing anæsthesia by the application to the part of tampons, made of cotton and floss silk and covered with silk gauze, which have been impregnated with chloride of methyl. This impregnation is effected by projecting a spray of chloride of methyl upon the tampon, or by soaking the tampon in the liquid. The greatest merit of these tampons is the fact that they hold the liquid better than any absorbent which has yet been used. In applying them, the tampons are held in forceps made of wood or ebonite, which materials are poor conductors of heat. The process which M. Bailly has devised he calls by the name of "Stypage." In order to manage the liquid chloride of methyl, Bailly has designed a simple apparatus, to contain and convey it, composed of a glass tube about five inches long sealed in a test-tube in such a way that the tube is in a vacuum produced with an air-pump or by means of carbonic acid and potassa. With this apparatus the liquid can be easily carried about, and used to impregnate the tampons. These are applied directly to the part to be anæsthetized, and can be used in such a size and for such a length of time as is exactly suited to the purpose intended. Bailly has carefully studied the effects produced by this method, and has recently (January, 1888) reported them to the Académie de Médecine, which has just received the report of a Commission endorsing the views of M. Bailly. The latter states that an application of one or two seconds

produces local stimulation, followed by a reactive congestion. If the tampon be applied for a little longer time it produces a marked local pallor and commencing anæsthesia. Prolonging the application for a few seconds more produces whiteness and stiffness of the skin, and an anæsthesia sufficient for minor operations. A still longer application produces blistering, and even an eschar, due to absolute freezing.

The varying results secured in this way have suggested a variety of therapeutical uses for this method, in addition to the production of anæsthesia for surgical purposes, all of which are described by Bailly in his paper published in the *Gazette Hebdomadaire*, Feb. 3, 1888, and by the Commission referred to, in its report, published in the *Bulletin de l'Académie de Médecine* for Jan. 31, 1888. We have not space in which to go into the details of the therapeutic indications for "Stypage," to which we may refer at another time; but we desire to call the attention of our readers to it, as we believe it is likely to prove more than a mere novelty in practice. If half the hopes of its inventor, and of his French colleagues are realized, it has a large field of usefulness before it; and it is well that American physicians and surgeons should be informed as to its possible applications and test its merits for themselves.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

PROTOBIOLOGY; OR, THE PHILOSOPHY OF LIFE. By Joseph McEwen, M.D., 8vo, pp. 101. Philadelphia: Phillips & Williams, 1887.

In the preface of this little book, the author asks for indulgence, on the ground of sincerity, and states that if his design falls short of the purpose intended it will not be for lack of purity of motive, but for lack of judgment. Such an announcement almost disarms criticism. But, having examined this book with some care, we have failed to discover what use it can be put to. It is straightforward, and may be clear to the author; but, to be candid, we cannot make out what it means. This may be our fault or misfortune, but it is a fact.

THE CHILDREN OF SILENCE; OR THE STORY OF THE DEAF. By Joseph A. Seiss, D.D., LL.D. 8vo, pp. 208. Philadelphia: Porter & Coates, 1887.

The author of this book, besides being a clergyman whose preaching has proved acceptable and useful to a large number of people, is one of the Directors of the Pennsylvania Institution for the Deaf and Dumb. His book has grown out of studies undertaken to fit him to discharge his duties at this institution intelligently. It was an admirable idea to give others the benefit of these studies, and the example Dr. Seiss sets is one which other managers of public institutions might well follow. If all such men made such thorough studies of the objects of their charitable labors, the result could not but be in the highest degree beneficial.

Having said this much as to the spirit of the author of this book, we have but little space left in which to speak of its character. This may be described, however, as most admirable. The whole subject of the nature, causes, manifestations and treatment of deafness, and of deaf-mutism is thoroughly discussed, and in a manner as attractive as it is instructive. One rises from a perusal of the book with an increased sympathy for the unfortunate class it treats of, and a clearer understanding of what may be done to relieve their sad condition.

TRANSACTIONS OF THE AMERICAN DERMATOLOGICAL ASSOCIATION. Eleventh Annual Meeting, 1887. 8vo, pp. 49. Boston: S. J. Parkhill, 1887.

The proceedings of the American Dermatological Association are interesting reading. One of the most interesting papers presented at this meeting was that of Dr. J. E. Atkinson, of Baltimore, on "Erysipelas in Infants," which led to a discussion which indicated that the disease is not contagious, or, if it is, only in a very limited way. Dr. James C. White, of Boston, also stated that for the past four or five years he has given no internal remedies in the treatment of erysipelas, and has never seen a case in which the eruption did not disappear in four or five days. Dr. J. Nevins Hyde, of Chicago, endorsed this pratice. Dr. Atkinson believes in using the tincture of the chloride of iron.

Among other interesting papers presented was one on "Dermatitis Herpetiformis" by Dr. L. A. Duhring, one on "Medicated Rubber Plasters" by Dr. H. W. Stelwagon, and one on "Salt Baths" by Dr. Henry G. Piffard.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY. Vol. 12. For the Year 1887. 8vo, pp. 512. New York: D. Appleton & Co., 1888. Price, $5 00.

It would be impossible, in the space at our disposal, to give any idea of the contents of this handsome volume, which, like its predecessors, is a monument to the executive and literary ability of the Fellows of the American Gynecological Society. This Society is one which reflects great credit upon the medical profession in America, and contributes to making our country foremost in every effort for the amelioration of the lot of suffering woman-kind.

THE RULES OF ASEPTIC AND ANTISEPTIC SURGERY. By Arpad G. Gerster, M.D., Professor of Surgery at the New York Polyclinic, etc. Illustrated with two hundred and forty-eight engravings and three chromo-lithographs. 8vo, pp. xii, 332. New York: D. Appleton & Co., 1888. Price, $5.00.

The title of this magnificent book gives no adequate idea of its contents. It contains, in fact, not only an admirable account of the theories and certain methods of aseptic and antiseptic surgery, but also a detailed description of the mode of procedure in a large

number of surgical operations, and of the appliances used in their after-treatment. The methods of operating are those most approved by the best surgeons living, and are described in a thoroughly lucid manner. The surgical applicances recommended reflect equal credit upon the learning and ingenuity of the author, who goes into details which are useless to no surgeon, and may be of the utmost service to any who are not familiar with the great advances which have been made in this part of surgical work within the last few years.

Dr. Gerster's book does not cover the whole field of surgical practice. For example, it does not discuss the treatment of injuries or diseases of the skull and of its contents; but it does treat of various phases of operative surgery of the limbs, of the abdomen, of hernia, of tumors of the breast and neck, as well as of the treatment of gonorrhœa and syphilis. These various subjects are considered systematically, as far as is consistent with the main object of the book, which is to teach the method of aseptic and antiseptic surgery.

It is no small addition to the value of the text of Dr. Gerster's book that the illustrations of it are of a very high order of excellence. Most of them are reproductions of photographs by the phototypographic method, and wonderfully handsome and instructive. The work of the publishers, in preparing this book, is as creditable to them as is that of the author to him, the paper, printing and binding being of the very best quality; and we can and do recommend it very strongly to our readers, as we feel that it is a book which ought to be in the hands of every practicing surgeon.

Pamphlet Notices.

Shakespere and the Medical Sciences. By L. M. Griffiths, M.R.C.S. Eng. L.R.C.P. Ed. From the *Bristol Medico-Chirurgical Journal*, December, 1887. 32 pp.

Suicide in its Relation to Insanity. By John J. Reese, M.D. etc., Philadelphia. From the *Medical News*, January 21, 1888. 15 pp.

The Physiological Action of Kreatin, Kreatinin, and their Allies. By Thomas J. Mays, M.D., Philadelphia. From the *Practitioner*, vol. xxxix, No. 4. 8 pp.

The Treatment of Pulmonary Consumption, with a Report of Forty Cases. By Thomas J. Mays, M.D., Philadelphia. 16 pp.

The Differential Action of Brucine and of Strcyhnine. By Thomas J. Mays, M.D., Philadelphia. From the *Journal of Physiology*, vol. viii, No. 6. 13 pp.

Synopsis of the Second Hundred Cases of Urethral Stricture Treated by Electrolysis. By Robert Newman, M.D., New York. From the *Journal of the American Medical Association*, September 24, 1887. 15 pp.

—Mr. Griffiths' paper is his Presidential address at the fourteenth session of the Bristol Medico Chirurgical Society. It is not quite what would be expected from its title, as the author acknowledges in a short preface; but it contains a number of very interesting facts in regard to the medical characters alluded to by Shakespere. In the introductory portion Mr. Griffiths indulges in some general reflections, one of which is a rather severe, but not wholly groundless condemnation of which is called "collective investigations."

—Dr. Reese, in the course of his general experience and in his work as Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania, has had abundant opportunity to familiarize himself with such questions as the one he discusses in this pamphlet. In it he presents the reasons which seem to him to show that the act of suicide is not in itself an evidence of insanity, and that the common verdict that suicide is the result of temporary aberration of the mind is a charitable euphemism. The argument is convincing and the pamphlet is one of great interest and value.

—In 1886 Dr. Mays reported to the College of Physicians of Philadelphia the results of his study of the nutritive properties of certain beef-extracts and has followed this up with an attempt to ascertain what part of their nutritive property is to be attributed to their organic extractives. The pamphlet before us contains the results of his study, which lead him to attribute the nutritive value of beef-extracts to their contained kreatin, kreatinin, etc. We can heartily commend this essay to the consideration of all who are interested in this important physiological problem.

—The pamphlet of Dr. Mays on consumption, contains his address before the Medical Society of the State of Pennsylvania at its meeting in 1887, and presents briefly the author's views as to the nature and proper treatment of pulmonary phthisis. It may startle some of those who read his address to find how small a part of the cases of consumption Dr. Mays seems to attribute to tuberculosis; and others may wonder at a report which states that thirty-one patients with consumption recovered under a method of treatment here described.

—Dr. Mays' paper on Brucine and Strychnine contains the results of an investigation to determine whether the difference of pathological action caused by administration of these two alkaloids is one merely of degree, or of kind. Dr. Mays thinks that this difference is one of kind. The experiments which lead him to this conclusion are described in detail, and seem to justify it.

—Dr. Newman is an enthusiastic believer in the sufficiency of electrolysis for the cure of stricture of the urethra. The reprint before us contains an address delivered at the meeting of the American Medical Association, in 1887, which made a decided impression upon all who heard it. Dr. Newman describes results from his plan of treatment which explain the earnestness with which he pleads that it ought not to be sneered at; and, least of all, by those who have no experience in the use of electricity. It is true that want of personal experience does not necessarily unfit one to judge of a method; for if it did few could condemn garroting, or the practice of hari-kari. But the application of electrolysis to the treatment of stricture of the urethra ought not to be condemned by those who have not tried it, in the face of the claims made for it by those who have, unless it can be shown that what its defenders say is erroneous in point of fact.

—The *Pallmall Gazette* says that the Murchison medal of the Geographical Society of London, is to be awarded this year to Prof. J. S. Newberry, of Columbia College, New York.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—With the number for February, 1888, the title of the *Mississippi Valley Medical Monthly* was changed to the shorter, more distinctive and better one of *Memphis Medical Monthly*. The fact which we record furnishes us with a welcome opportunity to express our appreciation of this excellent journal and to wish it continned and increased success.

—The *Quarterly Review of Narcotic Inebriety* is an octavo, the first number of which is dated January, 1888, and contains twenty-four pages. It is edited by Dr. J. A. Loveland, Gilsum, N. H.; price, $1.00 a year. It is devoted to the subject indicated by its title, and gives promise of usefulness. The number before us bears strong testimony to the propriety of treating morphinomania by rapid diminution and speedy withdrawal of the doses of this drug.

—The *Albany Medical Annals* began its ninth volume in January, 1888, and appeared in a new form and considerably enlarged. From having been merely a Bulletin of the Medical Society of the County of Albany, N. Y., it now becomes a general medical journal, to be issued monthly; price, $1.00 a year. The contents of the first two numbers for the year are interesting; and we wish it success.

—*Book Chat* is a twenty-four-page magazine, published monthly by Bretano's, New York; price, $1.00 a year, each number containing a certain number of extracts from new books, a catalogue of new publication, and a classified index of current periodical literature.

—*The American Anthropologist* is a new journal published under the auspices of the Anthropological Society of Washington, D. C., forming the continuation of its "Transactions." It is to be issued quarterly; price, $3 00 a year. The first number, dated January, 1888, contains sixty-nine octavo pages, and four original articles.

—The first number of the *Petite Revue d Obstetrique et d'Hygiène du Premier Age*, was issued in Paris, January 29, 1888.

Correspondence.

Quick Getting-up after Confinement.

Editor Med. and Surg. Reporter:

Sir:—The *Boston Medical and Surgical Journal* has been reporting some remarkable cases of speedy recovery after childbirth, and I would like to report one which occurred in my practice.

In May, 1883, Mrs. T., who expected to be confined early in June, made arrangements to move with her family, a husband and two small children, from Danvers, Mass., to a town in Maine, one hundred and seventy-five miles distant, expecting to get settled there before her confinement. On the 19th their goods were all packed and sent to the railroad station, and they were ready to start on the first train the next morning. A borrowed mattress, laid on the floor, afforded lodging for the night. At two o'clock in the morning labor came on, and I delivered the woman at 7 o'clock, after a painful confinement. Before I took the placenta away, she said: "I have been cheated out of going today; but I will go to morrow." The afterpains were so severe that I was sent for, and had some difficulty in relieving them. In the afternoon I found her dressed and sitting up, but crying bitterly. Supposing she was still in pain, I was about giving her another dose of anodyne, when she said she was not suffering. After a while I found that the cause of her grief was that her husband was drinking. I intended visiting her early the next morning, and if any attempt was made to go, I would prevent this. I was a few minutes too late, however, and found that the bird had flown, with her drunken mate and all. I afterwards learned that she reached her destination at 6 p.m., having traveled all day. The next year she was back in Danvers, with her three children and husband, looking as young and fresh as ever. She has had one or two children since, and is now living in this town.

Yours truly, W. G. Frost, M.D.
Danvers, Mass.,
Feb. 15, 1888.

Remarkable Treatment for Elongated Uvula.

Editor Med. and Surg. Reporter:

Sir:—Enclosed find a slip of paper, written by a colored man of some education. I showed it to a colored doctor who can't read or write, but who practices under the ten year law, regulating the medical profession of Indiana; said doctor told me that he cures such cases by taking the longest hair on top of the head, and pulling the throat and soft palate up to the roof of the mouth, after which he ties both with a silk thread to the last vertebral bone, keeping them there till the throat and palate become systemized in their proper place, when the patient is sound and well. Then he cuts the thread from the bone, and the hair close to the scalp. Yours truly,

Evansville, Indiana. J. Pirnat, M.D.
Feb. 4, 1888.

Spurious Hydrophobia.

Editor Med. and Surg. Reporter:

Sir:—I was greatly pleased with your editorial on hydrophobia in the Reporter for December 24. I am of the same opinion as

to the rarity of genuine hydrophobia, if there be such a disease; and it calls to mind a case which was also alleged to be hydrophobia. A young man of this city was bitten by a dog long known to be cross and surly, and was soon afterward shot. The story now spread that the dog was mad. In a short time the young man began to act strangely; was unable to eat or drink, had spasms, barked like a dog, etc. I did not see him at the time, but several physicians of this city saw him, and it was alleged that he was mad; one or two specialists from New York also came up to see him. Two or three years afterward I became acquainted with him, and attended his family for a time, and he then told me how he was treated. He said every one was afraid of him, and he was kept under the influence of morphine and ether to such an extent that he hardly knew what he said or did; finally, some one gave him a large emetic, followed by a powerful dose of physic, and he rapidly recovered. He has since left the place; but I shall try to get the full details of this case, as it is one more in the long list of fabulous cases of hydrophobia. He would undoubtedly have died, if he had not been relieved in the way that he was.

Yours truly, C. L. Dodge.

Kingston, N. Y.,
February 11, 1888.

Electrolysis instead of Oöphorectomy.

Editor Med. and Surg. Reporter:

Sir:—Because of the conservatism with which many physicians regard the removal of the ovaries, as well as the risks attending this surgical measure, I wish to ask the profession, through your columns, if *electrolysis* may not be resorted to for the purpose of destroying the functions of these organs, when not affected by diseases which would preclude this operation—if there be any such diseases.

If this less heroic measure proves as effectual as, and more safe than recourse to the knife, multitudes of women will be restored to health, now doomed to lives of chronic invalidism. This class includes, *First*, Those whose sufferings are directly due to the performance of the functions of the ovaries. *Second*, Those who, being invalids, are held to this condition by the depressing influence exerted by menstruation. *Third*, That very large number of women whose distressing symptoms are legion *during the establishment* of the menopause.

In view of the fact that in the majority of cases medication not only fails to relieve, but when constantly used has a deleterious effect on the general health of the patient, I am desirous of learning the opinions of gynecologists in relation to this method of treating the ovaries in order that a cessation of their functions may be effected and the patient be cured.

Yours truly,

H. Augusta Kimball, M.D.

Philadelphia,
February 20, 1888.

Removal of Duty on Instruments, etc.

Editor Med. and Surg. Reporter:

Sir:—At the annual meeting of the Georgia Medical Society, held January 3d, 1888, the following resolution was unanimously carried:

Resolved, That the corresponding secretary enter into correspondence with the medical journals of the country, in order to enlist their influence in support of the movement to remove the import duties from all medical and surgical instruments and appliances, including those used in the diagnosis as well as treatment of disease, so that they may be furnished to those needing them at the lowest possible price.

In compliance with the above resolution, I wish to solicit your earnest attention and a notice in your publication, which will claim the attention of your readers, hoping that your country readers, especially, will appreciate the truth and importance of our proceedings. Perhaps the statement of a few facts will assist the reader in realizing the extent of the grievance and the justice of the plea for which we ask co-operation.

First. Physicians are at the mercy of instrument makers in regard to price, make and quality of finish, because of the lack of sufficient competition.

Second. The price of instruments made in this country is out of proportion to that paid for similar instruments on the continent of Europe.

Third. Surgical instruments and appliances are so costly that but few doctors entering the profession can provide themselves with an outfit adequate to carry on a general practice. At present prices it is impossible for a country physician's income to sustain his investing in costly instruments, and as a result many simple cases, such as retention of urine, foreign bodies in nose or throat, deep-seated abscesses, etc., all of which could be relieved at once with the proper instruments, must either die from the immediate cause or from the effects of time lost in seeking skillful manipulation, or else they are frequently crippled and disfigured, because

the most intelligent help, though patiently given, is itself crippled for want of proper instruments.

Fourth. The cheaper grades of instruments are either antiquated or so poorly made that they may prove a cause of failure in operations, sapping, as it were, the natural inclinations to surgery in its inception.

Fifth. European instruments are from 25 to 75 per cent. cheaper than ours, and their introduction into the market will enable the mass of doctors to buy those of prime necessity, will bring down the price of home-made appliances, and oblige the makers to use good material and put a better finish to their work.

Sixth. The removal of import duties on surgical and other instruments used by the profession, and on medicines in general, will produce the same results as we all know it did on the article of quinine.

Respectfully, J. C. LeHardy,
Cor. Secretary Georgia Med. Society.
Savannah, Ga., January, 1888.

Notes and Comments.

The Results of High License in Chicago.

In a letter to Mr. John B. Pine, of New York, published in the *N. Y. Evening Post*, February 17, 1888, Mr. William J. Onahan, of Chicago, says:

"I send you the desired table of statistics of arrests by Chicago police for a number of years past, as shown in annual report of Police Department. I am informed that journals in New York hostile to high license have attempted to demonstrate that high license in Chicago is a failure—that far from aiding to diminish drunkenness it has on the contrary served only to increase the evil; and that arrests from this cause—"drunkenness"—have increased enormously under the operation of high license. I am justified in saying that no one could be found bold enough to publish this statement in Chicago. These assertions are not true in fact; neither can they be justified as an inference from any collocation or manipulation of figures, official or otherwise. The substantial and incontrovertible fact is that high license has arrested the multiplication of saloons in Chicago—that whereas in 1882–3, under a license of $52 per year, we had 3919 licensed saloons; in 1887–8 the number is substantially no greater, while the population has increased from 500,000 to 900,000, and the city has extended its limits on every side, so that it is not unreasonable to assume we should now have 6000 or more saloons except for the intervention of a high license. Neither is it true that drunkenness has increased out of all proportion these years, as it is claimed the arrests show. They show no such thing. In fact the police reports for several years do not show arrests under the distinctive head of "drunkenness" or "drunk and disorderly" at all. Arrests made for these offences are included under those of "disorderly conduct," which embraces a variety of other offences as well. Plainly, therefore, any use of the figures such as suggested would be misleading, and certainly cannot be sustained. Moreover, I have the authority of the General Superintendent of Police to corroborate my statement in this regard.

No, high license is not a failure in Chicago. It has driven out of existence the pest of the home, the curse of the family—the bar in the family grocery, which is no longer seen here. Very many of these places never had licenses at all. High license checked at once the extension and multiplication of the saloon traffic, and it is no secret that the results in favor of high license would have been far more marked had the law been enforced and carried out according to its plain spirit and intent. Had the license fee, $500, been made payable in advance in one payment, instead of in three-period payments, I am persuaded that the number of saloons would have been down to below 3000.

High license produces a revenue (nearly two millions) more than sufficient to cover the entire outlay for our police.

High license has aided in lifting us out of the quagmire of saloon politics, though much yet remains to be done in order that our emancipation may be complete. But high license will not do everything, nor is it alone the cure for the evils growing out of the drink plague.

High license diminishes temptations, lessons opportunities to drink, and to that extent is a boon and a blessing, but it does not remove the appetite for drink. This latter is to be effected by moral suasion, by religious teachings, through the influence of example. As a citizen I regard "high license," coupled with strict regulation of the saloon traffic by the municipal authorities, as an important auxiliary in the work of temperance reform, as an aid towards better government of cities, and I hail with satisfaction any and every reasonable effort to level upwards in this direction. Finally, I can say without fear of successful contradiction, that the people and press of Chicago are on the side of high license, and if there is to be any change here,

it will surely be towards higher license and stricter regulation for the saloon taffic.

A New Deodorizer for Iodoform.

Louis Genois writes to the *Medical News*, February 18, 1888, advocating the use of purified naphthaline as a deodorant for iodoform. He declares that it will mask the characteristic odor of iodoform so effectually as to challenge detection by the sense of smell alone. He suggests the following formulæ:

℞ Naphthalini purificat.....gr. viiss
Turmeric .....gr. iss
Iodoformi.....gr. xci
Rub together until thoroughly mixed.

℞. Iodoformi deodorat (as above).. ..ʒii
Olei amygdalæ.....fʒii
Lanolini.....ʒvss
M.

For ordinary pharmaceutical purposes the deodorized iodoform can be used instead of the simple drug, but in making an ethereal solution the turmeric should be left out, as it is not soluble in ether.

Formula in Bright's Disease.

Semmola's formula for albuminuria dependent on nephritis, is:

℞ Sodii iodidi.....gr. xv
Sodii phosphat.....gr. xxx
Sodii chloridi.....gr. xc
M. Sig.—Dissolve in water, and give in the course of twenty-four hours, either alone or with milk.

Emulsion of Terebene.

Mr. J. W. England recommends the following formula in the *Amer. Journal of Pharmacy*, February, 1888:

Terebene,.....
Ol. gossyp. sem.....āā ♏clx
Pulv. acaciæ ..... ʒvj
Pulv. sacchari..... ʒij
Aquæ q. s. fiat..... fʒiv
Dose—1 to 2 teaspoonfuls (=10-20 drops).

The product is a milk-white, perfectly suspended liquid, having the odor, and bitter turpentine-like taste of terebene, and is miscible with water, without separation.

This method, of previously admixing with cotton-seed oil is very useful in suspending volatile oils, especially the oils of gaultheria and eucalyptus, which have come into such general use within the past year, and it is more economical, in that a much less quantity of acacia is necessary for suspension, but it is of no value whatever in the emulsification of such liquids as ether and chloroform, so that we are compelled to fall back in their administration, upon previous admixture with milk, as each dose is given; a temporary expedient only, possibly, but one which has certainly yielded good results.

NEWS.

—The *Lancet*, Feb. 11, 1888, reports the death of Dr. Hyacinthe Sauveur, Emeritus Professor in the University of Liège, and last survivor of the old Faculty of Medicine reorganized in 1835.

—By the will of the late Dr. Robert Nebinger, of Philadelphia, a sum of money estimated to be about $300,000 is bequeathed to the Sisters of the Order of St. Francis, for the erection and maintenance of a hospital.

—The number of hospitals in Paris, remaining under the care of religious orders is steadily diminishing. It is said to be the settled policy of the Municipal Councillors to substitute lay nurses for the nuns who have heretofore had charge of the nursing. In accordance with this policy the Augustinian nuns have just been expelled from the Charité Hospital.

—An attempt was recently made in Dublin to photograph a lioness with the head of the tamer in its mouth. The animal, wearied by the tension of her maxillary muscles, or scared, it may be, by the sudden flash of the magnesium light, tore the woman's cheek completely open. Fortunately, no more serious injury resulted, the lioness being beaten off in time to prevent a threatened catastrophe.

—The third Congress of French Surgeons will be held in Paris from March 12 to March 17, 1888. M. Verneuil will preside. The principal subjects for discussion will be 1. The methods of treatment of gun-shot wounds of the viscera. 2. Value of the radical operation for hernia as regards permanent cure. 3. Chronic pleural effusions and their operative treatment. 4. Recurrence after operations for tumors—its causes and prevention.

—The department of general and orthopædic surgery, of the Philadelphia Polyclinic has been reorganized as follows: Professor, H. Augustus Wilson, M.D.; Adjunct Professor, A. B. Hirsh, M.D.; Chief of Clinic, J. F. Bower, M.D.; Assistant, William S. Shimer, M.D.; Mechanician, Mr. A. Gustaf Gefvert. Massage and Swedish Movements, Mr. K. W. Ostrom, from the University of Upsala, Sweden; Miss Anna Jonsson, graduate of the Royal Central Gymnastic Institute of Stockholm, Sweden. A machinist's work shop, with all the necessary tools has been fitted up in the college building, so that the fitting, applying and altering of surgical-mechanical appliances can always receive the combined attention the of surgeon and mechanician. The wards of the hospital afford facilities for cases requiring house treatment.

HUMOR.

THE EMPEROR OF BRAZIL wears a horse-chestnut tied to his neck to keep off evil spirits, and it has been a great success.

PASSENGER (on street-car, alarmed)—"Madam, do you feel a fit coming on?" Madam (haughtily)—"No, sir; I'm trying to find my pocket."

THE AUGUSTA *Chronicle* has invented a way for people to remember what a cold-wave flag looks like. The *Chronicle* says "the flag has a black lozenge in the centre; this is for bronchitis."

WIFE (looking up from her book)—"You know a great many things, John. Now, what do you think should be done in a case of drowning?" Husband—"Have a funeral, of course."—*Boston Courier.*

DR. PELLET—"So Scalpel set your broken arm?" Patient—"Yes, sir." Pellet—"What were his charges?" Patient—"Twenty dollars." Pellet—"Robbery, sir—downright robbery! I'd have amputated it for $25?"

"I WONDER WHERE they get camphor gum?" said little six-year-old Eddie Post. "Why, laws 'ee! Don't you know that? and you in the first reader, too?" replied his playmate, Nellie Green, aged five. "Well, I tell you. You see the Arabs chases the camphors over the deserts till they catches 'em; an' they knocks 'em down an' cuts their gums off."

OBITUARY.

SAMUEL HEY, F.R.C.S., ENG.

Mr. Samuel Hey, of Leeds, England, died February 21, 1888, aged 73 years. He was the fourth link in a chain which has stretched in one unbroken line for 150 years, and which has inseparably bound together the name of Leeds and the practice of surgery. To his predecessors in the surgical world Leeds owes much of the great surgical reputation which she enjoys all the world over, and in Mr. Samuel Hey they were followed by a worthy successor.

JOHN K. KNORR, M.D.

Dr. John K. Knorr died February 15, 1888, at his late residence, in Philadelphia. He was born at Rising Sun, and commenced active life by teaching school. Soon after he entered the medical department of the University of Pennsylvania, from which he was graduated in 1835. Since then he had been actively engaged in the practice of medicine. While prescribing for a patient in his office, he fell dead. He was 76 years old at the time of his death, and leaves three children, two sons and a daughter.

JAMES CRAIG, M.D.

Dr. James Craig was born in the city of Glasgow, Scotland, January 22, 1834. He came to the United States when seventeen years old. He entered the office of Dr. J. H. Stewart, of St. Paul, Minn., where he prosecuted his studies for about two years. In 1859 he came to New York, and matriculated in the medical department of the New York City University, and was graduated therefrom in 1861. He began practice in the spring of 1861 in Jersey City, where he remained actively engaged until within a few days of his death. His specialty was obstetrics, in which he was very successful. He leaves five of his family, three daughters and two sons. Dr. Burdette Craig, the eldest of the family, succeeds to his father's practice.

D. MAY, M.D.

Dr. D. May, died in Findlay, Ohio, February 16, 1888. He was a practising physician in Fairfield county before the war of the rebellion, and had a wife and two children when he left, in 1861, to join the Union army. His long absence led his family to believe him dead, and his wife remarried. Upon the death of his wife Dr. May returned to Ohio and made himself known to his children. Dr. May was a resident of Findlay for many years and was well known all over Ohio.

SENECA B. THRALL. M.D.

Dr. S. B. Thrall died in Ottumwa, Iowa, January 20, 1888, at the age of 56 years. He began the study of medicine with his father in 1849. He was a member of the Iowa State Medical Society, and its Secretary from 1870 to 1877.

No changes in the Medical Corps of the Navy, during the week ending Feb. 25, 1888.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ended Feb. 25, 1888:

L. L. Williams, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon from Feb. 10, 1888. Feb. 23, 1888.

J. O. Cobb, Assistant Surgeon, appointed an Assistant Surgeon, Feb. 21, 1888. Assigned to duty at Marine Hospital, Chicago, Ill., Feb. 25, 1888.

J. B. Stoner, Assistant Surgeon, appointed an Assistant Surgeon, Feb. 21, 1888. Assigned to duty at Marine Hospital, New York, N. Y., Feb. 23, 1888.

A. W. Condict, Assistant Surgeon, appointed an Assistant Surgeon, Feb. 21, 1888. Assigned to duty at Marine Hospital, Chicago, Ill., Feb. 23, 1888.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

Clinical Lecture.

CONSUMPTION.

BY JOHN A. ROBISON, A.M., M.D.,
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, WOMAN'S MEDICAL COLLEGE; ATTENDING PHYSICIAN TO COOK COUNTY HOSPITAL, ETC., CHICAGO, ILLINOIS.

[Reported by William Whitford, M.D.]

Gentlemen:—We have to-day a group of cases which exhibits the various manifestations of consumption. It is a disease that assumes varied forms. The case before you is one of incipient phthisis, and we commence with him first simply because we desire to make a few remarks with reference to the diagnosis of these cases in their various stages. In the first place, I will state that when you examine a patient, suspecting lung trouble, there are certain precautions which you must observe, to prevent an error in diagnosis. For instance, you must remember this fact, that you will not hear the expiratory sound in all cases. It is only in about three-fourths of the cases that you can hear any expiratory sound. Another point is the relation in the length of time between inspiration and expiration, which varies in different patients. Expiration is usually one-fifth as long as inspiration. You find, sometimes, cases in which the expiratory sound is one-third to one-fourth as long as the inspiratory sound. Now, as a matter of fact, expiration is really four-fifths as long as inspiration, because it takes nearly as long to expel the air from the air-cells as it does to fill them. But there is a great difference between inspiration and expiration as regards the length of time these acts occupy, so far as your sense of hearing is concerned; consequently when you listen over the chest you will find you can generally hear inspiration quite readily, while expiration is not so readily heard, and does not occupy the whole length of time during which the air is passing out of the lungs. If we represent by figures the length of time which inspiration and expiration occupy, as well as the period of rest, they would stand in about this ratio: Inspiration occupies five-tenths of the time; expiration about four-tenths of the time, and then there is a pause between expiration and inspiration, which is the period of rest, occupying about one-tenth of the time. But on auscultation these figures would be changed, as expiration would appear to be three or four times longer than inspiration. And you must remember that patients do not follow test figures. You may meet persons who have sound lungs and the expiratory sound is nearly as long as the inspiratory. Therefore, do not be too ready to base a diagnosis of there being pulmonary disease present when there is prolonged expiration.

There is another point, and that is to determine the *quality* of the expiratory and inspiratory sounds. The inspiratory sound is a soft, breezy, low-pitched sound. When you listen over the chest and hear it, it gives you the idea of a soft current of wind passing through the chest. On the other hand, you are taught that the expiratory sound is higher in pitch. By some authorities it is claimed to be lower in pitch. If you will listen carefully over a healthy chest you will find that the difference between the expiratory sound and the inspiratory sound is this: The inspiratory sound is soft, breezy or vesicular in quality, and low-pitched, while the expiratory sound has less vesicular quality, is more like a blowing sound, with a lower pitch. Whenever you find a case in which the expiratory sound is longer than the inspiratory, and its pitch is high, and its quality blowing, you may be certain it is due to consolidation of lung tissue.

There is one point I wish to mention, and one that is not often referred to, and yet you would learn it yourselves by practice, and that is the presence of a sound from a peculiar muscular vibration which takes place, especially during inspiration, in the muscles of the chest wall. This sound is termed muscular susurrus, a word which indicates the vibratory sound. This sound approximates somewhat in character the inspiratory sound. It is a soft, low-pitched, wavy sound, and listening over the chest wall in patients who take a full breath or exert themselves, you may be inclined to think you hear the inspiratory sound and may mistake it for the respiratory sound, and may think it evidence of a healthy lung, when in reality broncho-vesicular breathing may be present. The way to prevent that is to have your patient breathe easily, or do not let him take full breaths, so that you may be able to hear the respiratory sound without this muscular vibration. You may also prevent it to a certain extent by placing the muscles in a state of relaxation. The ordinary direction in examining the chest is for the patient to place the muscles of the region being examined in a state of tension; for instance, if you are listening over the anterior portion of the chest, have the patient place his hands behind his back. By so doing you get a more pronounced susurrus. In case you get this sound simply have your patient place himself in some other position, so as to put the muscles in a state of relaxation.

This patient, a male, aged 22, an Italian, and a laborer, has been ailing one year. He says he has had a hacking cough, has lost flesh, at intervals has night-sweats, and sometimes is feverish.

The physical signs in this case are flattening of chest at the right apex, loss of motion on the right side, dulness to a slight degree, and increased vocal fremitus over the right infra-clavicular region, with broncho-vesicular respiration. This is a well-marked case of pulmonary tuberculosis in the first stage.

The physical signs you obtain in the first stage of phthisis depend much upon the amount of consolidation of the lung. If there be a limited amount, and the disease is of short duration, there would be very little difference in the conformation of the chest walls; but if the disease has been of quite long standing, and the amount of consolidation is considerable, there is consequently a retraction of the lung tissue, and as a result of that the deprived air-cells become collapsed and that characteristic flattening at the upper part of the apex occurs. Associated with this flattening there is loss of motion because that portion of the lung does not expand fully.

However, you may meet cases in which you get none of these signs, and yet you can, in the majority of such cases, make a diagnosis in the following manner: supposing in this case the only physical sign present was mucous râles over a limited area only on one side; in the absence of injury of any kind to the lung producing localized bronchitis, such as introduction of irritants into the bronchial tubes, you can almost certainly say that the case is one of incipient consumption; and thus a diagnosis could be made before the ordinary physical signs had appeared, and at a time when you could most advantageously place your patient under the proper treatment. I believe there is truth in the statement by Buhl, that bronchial walls often become inflamed, and that this is accompanied by parenchymatous pneumonia in a limited area. Such a condition of the lung tissue would give rise to such signs as I have often noticed in cases which eventuate in consumption of the lungs. This sign is, therefore, a very important one, since it enables us to forecast the future, and being forewarned we can be forearmed therapeutically.

A Case of Acute Phthisis.

This second patient presents the disease in a more advanced form. The patient, a man, is 19 years of age, and was admitted to the hospital February 2, 1888. On admission his pulse was 124; temperature 103°; respirations 30. This morning, February 3, at 3 A.M. his pulse was 124; temperature, 104.2°; respiration, 32. Family history good. As to his personal habits, he drinks moderately. He had pneumonia eleven years ago, but otherwise has been in good health until the commencement of this illness. Present trouble commenced with a severe chill about a month ago, the chill lasting about eight hours, and being followed by a severe headache, cough, dyspnœa and pain in the chest; no blood in the sputum, which has always been yellowish-white and frothy. Bowels have been constipated; has had night-sweats from the commencement of the disease; little or no appetite. On admission, patient appeared emaciated; face was florid; tongue was clean, but flabby; skin dry.

Gentlemen, you will notice that dyspnœa is severe and that cyanosis is appearing, the lips and face being bluish. His tongue has a raw appearance, indicating great debility and fever.

This case exhibits a form of the disease in which the deposit is undoubtedly miliary tubercle, and from the rapidity and shallowness of the respirations both lungs must be thickly studded with them. There is no loss of motion, no dulness on percussion, no bronchial breathing, nor, in fact, any of the signs which indicate consolidation of the lung; but listening over the chest we hear fine subcrepitant râles, with puerile respiration. What does that indicate? It indicates that the bronchial tubes, especially the smaller ones, are inflamed. Then on both sides we can find in two or three different places small friction sounds. What do they indicate? They indicate that miliary deposit has taken place beneath the pleuræ. You notice, furthermore, that the patient complains of having pain in the abdomen. I have no doubt there is also, a deposit of miliary tubercle in the peritoneum. Breathing over both lungs is harsher than normal, shallow and frequent. All these physical signs point to the fact that there is a miliary tubercular deposit throughout the whole lung tissue, involving the pleura, and perhaps the peritoneum, or the serous coats of the intestines.

In this case the symptoms are a high temperature, a rapid pulse, and frequent respirations. The patient has lost flesh rapidly. The history of this case will undoubtedly be this: That the high temperature will continue, no matter what course of treatment may be instituted, and the case will continue to be one of progressive emaciation and exhaustion, finally terminating fatally.*

The method of making a diagnosis between cases of acute phthisis and phthisis due to gray tubercle is very different. In a case of consolidation of the lung, or what is known as "old-fashioned consumption," you make your diagnosis by well-marked physical signs; whereas in a case of miliary tubercle of the lung you make it more from the symptoms than from physical signs.

Phthisis Complicated with Tubercular Laryngitis.

Our next patient was admitted to the hospital February 2, 1888. He had bronchial trouble some years ago. Last year he suffered from mercurialism, mercury having been given him for specific trouble, whence he dates the active onset of his present illness. He became hoarse; at times breathing would be labored, and deglutition painful; sometimes only fluids could be taken. He has a dry cough; no expectoration; has lost much flesh; has nocturnal seminal emissions, diarrhoea, and lately night-sweats. The character of his cough is hoarse and laryngeal, while his voice has almost failed, he not being able to speak above a whisper. On laryngoscopic examination we see there is ulceration of both vocal chords, extending to the anytenoid cartilages. This accounts for the character of the cough. We may get the same kind of a cough in paralysis of one or both vocal chords of the larynx, in cases of ulceration, loss of tissue of the vocal chords, or interference with the action of the muscles of the larynx.

The lesion which exists in the lung in this case is in the form of a cavity in the right apex. The characteristic physical sign is cavernous breathing, which is present in this case in a typical form.

By the way, I should have remarked that his occupation has been that of theatrical singer, and the fact of using his voice every night, and perhaps during the day, and also being exposed to draughts, combined with the ptyalism, no doubt inflamed the latent tubercles, and hastened the full development of the disease.

When ulceration of the vocal chords occurs deglutition is painful and exceedingly difficult. It is more difficult to swallow dry than soft articles of food, and the patient finds it harder to swallow liquids than soft mush, or food of a similar nature; consequently in our treatment we have to order bread soaked in milk, or pudding, or some article of food that has a like consistency.

I read an article in a medical journal some time ago (referring to cases of laryngitis, or ulceration of the larynx, in which patients had difficulty in swallowing) to the effect that the difficulty of swallowing could be obviated by having the patient drink out of a bowl with the head lower than the body. I tried that in the case of a young lady with tubercular laryngitis, and it was a success. I simply had her lean over the edge of the bed, and had her swallow with the head lower than the body, and the result was she could swallow liquids quite readily in that manner. The explanation of it is supposed to be some peculiar action of the muscles and the force of gravity in aiding the closure of the epiglottis.

Cases of tuberculous laryngitis you will meet frequently when you go out to practice; and the question arises, what treatment can we institute for them? I presume there is no subject which has been more written upon by specialists than the treatment of tubercular

* A few days later this patient died, and the miliary deposit was found in the lungs, kidneys, liver, and in all the serous membranes.

laryngitis, and in which the results have been less fruitful in obtaining a treatment that is successful in curing the disease. The only thing we can attempt to do is to institute such treatment as will render the patient as comfortable as possible; and that comfort consists in the first place, in relieving the cough. This you can do by the internal administration of opiates or anodynes, remembering that too much of the opiates will cause dryness of the throat, and that itself is a source of irritation and discomfort to the patient. In the second place, constitutional treatment must be re-enforced by local treatment. The larynx should be cleansed thoroughly every day; oftener than that, if necessary, and at the same time some antiseptic remedy applied—as iodoform, for example—which is indicated, and recommended perhaps more than any other remedy in these cases. To relieve the pain in deglutition, we may apply a five or ten per cent. solution of cocaine shortly before eating. Krause, of Berlin, has extolled highly the use of lactic acid, while Rosenberg, of the same city, speaks in praise of menthol. In the third place, in certain cases, where the disease has progressed very rapidly and suffocation is imminent, the question would arise whether tracheotomy would be justifiable or not. The symptoms must be urgent, and the surgeon must be fully convinced that he will either prolong life or relieve suffering, before undertaking the operation. I do not consider it justifiable in this case at present, and we will therefore follow out simply local medication, being in readiness, however, at any time, to carry out any operative procedures that may be necessary.

A Case of Tabes Mesenterica.

J. L. was admitted January 5. Family history: One sister died of consumption. Two years ago he had an attack of rheumatism, during which time his ankles became swollen. February, 1887, his left leg was amputated on account of tuberculosis of the ankle-joint; he left the hospital in March of the same year, and has not regained his former health. He coughs a good deal, the sputum being of a yellowish color; the lower extremities become œdematous at times; the abdomen enlarges; micturation becomes more frequent; and at short intervals the patient suffers from diarrhœa. When first admitted into the hospital there was enlargement of the abdomen, a good deal of tenderness and diarrhœa at times; and while we are not able to find any tubercular trouble of the lungs, yet at the same time he is progressively emaciating, and the enlargment of the abdomen is increasing. We have no indication of the presence of dropsy. Making deep pressure through the abdominal walls, we can feel what seems to be enlargement of the mesenteric glands. It is one of those cases in which there was primary tubercular trouble of the ankle-joint, for which amputation was performed, and the tubercular disease has now appeared in the mesenteric glands. He has continuous fever, with progressive emaciation.

On the 9th, four days after admission, his temperature was 103.2°; morning of the 11th, 99°; evening, 100.8°. His temperature then remained about 99° or 99.8° until the 22d, when it rose to 100°. On the 25th, afternoon temperature was 100.8°, showing, of course, excessive waste of tissue. The prognosis is unfavorable. The case is an illustration of the manner in which tubercular disease may manifest itself.

Communications.

Typho-Malarial Fever, and Quinine.

BY JAMES W. PRICE, M.D.,
FORT SMITH, ARKANSAS.

For forty years, and most of that period engaged in active practice, I have been a close observer of the various diseases incident to the climate in which I have lived. I speak of the different forms of fever, and from an honest standpoint, I have long since come to the conclusion that they have not changed in grade or symptoms for a century. Typhoid, remittent, intermittent, and inflammatory types are exactly what they were one hundred years ago. Professional views, however, have undergone a wonderful development, and this has resulted in various experiments, not all of which have been to the advantage of the patients; and it is a serious question, whether or not diseases are cured with any greater success than they were in the days of our fathers? This interrogation may arouse the young men of the profession; but, we who have been long in service, and have fought many battles in the professional field, are not so apt to be entrapped by new names of diseases, or the numberless modern therapeutical agents.

I reside in a region where malaria is prevalent, and frightens many people into imaginary paroxysms of so-called typho-malarial fever. This is a form of fever which I should name inflammatory remittent, but our most

progressive medical brethern here insist upon the term typho-malarial. In regards to this, Prof. I. G. Jones, says: "Malaria is a generic term; typho-malaria is a misnomer. Both are calculated to mislead novices, and even old practitioners; therefore, I propose the good old term remittent. If we claim that it is due to miasm, we only plead our ignorance of its causes, as we do not know what malaria is." The term typho-malarial fever is of modern origin. Dr. J. H. Egan states that this title was given to the fever contracted by the U.S. troops in the Chickahominy swamp while investing Richmond. Dr. Woodard, who gave it the name, recanted his position, and regretted that an error should have gone uncorrected for ten years.

Alfred Stillé, Professor of Theory and Practice of Medicine, says: "Remittent or bilious fever, called lake, marsh, or jungle fever, is of all degrees of gravity. The course is made up of a series of paroxysms and remissions, with no intermediate periods of health; the paroxysms may be short, may be long, or almost continuous. Symptoms abate, but do not cease. If the fever tends to recovery, it changes to intermittent; if it tends to death, the patient sinks into the typhoid state. The typhoid state of malaria has been absurdly called typho-malarial fever."

The treatment of so-called typho-malarial fever is almost entirely confined in this country to the indiscriminate administration of quinine, not unfrequently in enormous doses. This error has grown out of the assumption that the disease is of malarial origin. All the cases which terminated fatally, have exhibited hyperemia of the brain, which in in my opinion, was the direct effect of quinine, and not due to the disease itself.

Dr. Atkinson, says: "The use of quinine in full doses in this fever is apt to produce torpor and congestion, attended with a slow pulse, profuse perspiration, inanimation, and a world of trouble to the doctor and danger to the patient."

H. G. Magee, M.D., says: "This fever is not influenced by quinine, so we must come to the conclusion that the name of typho-malarial fever is a misnomer."

Dr. Usher: "Like Dr. Thompson, I have had very poor success when I used and relied on quinine; it seemed to aggravate the case."

Prof. Binz, holds the theory that quinine reduces the temperature by weakening the power of the zymotic poison. He does not deny that quinine may kill by paralyzing the heart.

Peacock of London, and Niemeyer, have both given up the use of large doses of quinine. Quinine in large doses is unnecessary, useless, and often dangerous.

Benj. Edeson, M.D., says: "For some years physicians have been *quinine mad*, affected with what may be termed *cinchoniphobia*. The practice seems to have been, when in doubt, give quinine; give quinine any way. So the people have been dosed with it, and have been educated up to the belief that it is good for every ailment. So the public order it in pills, powders, tablets, and triturates, just as they do their potatoes and flour, and take it without a prescription, but with the *quasi* endorsement of the doctor that should it do no good, it would do no harm."

I cannot close this article without calling attention to the danger of indiscriminate administration of quinine to children, under the impression that it is a harmless agent. It will impoverish the blood by destroying its coloring matter. It is destructive to the nervous system by its powerful impression made upon the brain. Children will become sallow, anæmic, and predisposed to dropsical effusion which will end in premature death.

APEX EXPANSION VERSUS PURE AIR IN PULMONARY CONSUMPTION.[1]

BY THOMAS J. MAYS, M.D.,
PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC.

Next to the tubercle bacillus, impure air stands most prominent among the many agencies which have been assigned as the causes of pulmonary consumption. Innumerable plans and methods have been devised and proposed for improving the ventilation of our dwellings, hospitals, and workshops; volumes upon volumes have been written on the ill effects of breathing vitiated air; and the immaculate freshness of the country and mountain air has come to be universally regarded as a certain guarantee against pulmonary consumption. These, like many other popular notions, contain a germ of truth, but actually are delusive, inasmuch as they exaggerate the effects of a small evil, and afford a false sense of security against the real source of danger in the production of this disease. This we shall endeavor to show in the following pages.

At the very outset we desire it to be well understood that we do not in the least underrate the value of fresh, wholesome air in the prevention and treatment of pulmonary con-

[1] Read at the Meeting of the Philadelphia County Medical Society, February 22, 1888.

sumption, and while it is probably true that on the whole country people enjoy greater immunity from this disease than city people —though this is not proven on account of a lack of adequate statistics—yet we are convinced that the purity of the atmosphere plays a very small part in bringing about this probable result. If we are permitted to make a homely, hypothetical proposition, we will state that if two individuals who respire the same quantity of air, and who are equally well off so far as heredity, food, clothing, warmth, comfort, etc., are concerned, were both enjoined to maintain a sedentary and a stooped position of their bodies for an unlimited period, one inside of a house and the other outside in the open air, we have no reason for believing that the one inside will fall a victim to this disease sooner than the one on the outside. If it were true that this disease is the result of breathing a vitiated and impure atmosphere, how can we account for the fact that the inhabitants of Iceland, Greenland, Lapland and of other cold countries of the north, who live in dwellings which are notoriously wanting in ventilation, are practically exempt from this disease? Of the Icelanders, Mr. Warford Lock,[1] who is very familiar with these people and who speaks their language, says that their life is "one long exposure to the elements, and during the night they live in dwellings devoid of ventilation, and which, if not buried beneath the earth, are built of turf and often become grass-grown. A very bad feature being the excessive stuffiness of the common living and sleeping-room, when, owing to the absence of fires, the greatest possible crowding and plugging are necessary in order to maintain a tolerable degree of warmth." And yet Dr. Cullimore,[2] from whose work the above quotation is taken, says (p. 73) "that consumption in Iceland is never indigenous, but is always, when it does occur, imported from abroad and but seldom extends to the second native generation." On the other hand, it may be stated that the people of the tropical regions of the globe who enjoy an uninterrupted revelling in pure, fresh air, both day and night, winter and summer, are by no means free from pulmonary consumption. The only difference, so far as the physical life of these two classes of people is concerned, is that the warm climate, which produces such a luxurious atmosphere, also creates a tendency to physiological sluggishness and an indisposition toward physical exertion among its inhabitants; while the people of the cold and rigorous north are compelled to maintain the warmth and vitality of their bodies in great part, by day, through physical exercise, of which their occupations of hunting, fishing, herding, etc., give them a full share. It is also well-known that miners and laborers employed in coal mines, who continually respire an atmosphere which is not only loaded with impurities, but is damp and musty, suffer but very little from this disease.

One fact which lends color to the belief that pure air is such an essential element in limiting the ravages of consumption, is that those who occupy elevated or mountainous regions are less liable to this disease than those who live near the sea level. Thus Fuchs shows from extensive data that "at Marseilles, on the seaboard, the mortality from this disease is 25 per cent.; at Oldenburgh, eighty feet above the level of the sea, it is 30 per cent.; at Hamburg, forty-eight feet above the sea, it is 23 per cent.; while at Eschevege, four hundred and ninety-six feet above the sea level, it is only 12 per cent.; and at Brotterode, eighteen hundred feet above the sea, it is but 0.9 per cent." Carrying this line of observation further, it appears very probable that consumption is almost unknown among any native people who live more than 6000 feet above the level of the sea.

Now that which concerns us here chiefly is the reason why mountain climates are, as a rule, so free from pulmonary consumption. Is it because the atmosphere is pure and free from septic germs? This is hardly possible, for if it were true that the aseptic condition of the air played any very prominent part, why should the Icelanders, who nightly reek in a most filthy atmosphere; or the dwellers along the Nile, who, according to Mr. B. Phillips, live "in huts where the pure air has neither ingress nor egress, except through a small hole near the ground;" or the coal miners, who continuously respire a foul and poisonous atmosphere, all be comparatively free from this disease? Is it due to the general absence of humidity? We think not, for Bogota, the capital of the United States of Colombia, located on the Andes, near the equator, and at an elevation of over 9000 feet, is said to be entirely exempt from this disease, although dampness prevails to quite a large extent. We think there is much reason for believing that it is principally, if not entirely, on account of the attenuated condition of the atmosphere, and shall, therefore, at once proceed to consider the physio-

[1] The Home of the Eddas. S. Low, 1879.

[2] Consumption as a Contagious Disease. Ballière, Tindal, & Cox, 1880.

logical influence of high altitudes on the human body. It is estimated by Dr. Denison that at an elevation of 6000 feet, the surface of the body is relieved of nearly 7000 pounds pressure. When such an enormous weight is lifted from the body it is quite evident that its interior must also be markedly affected —the pulse is accelerated from fifteen to twenty beats per minute; the respiration is quickened from ten to fifteen breaths per minute; evaporation from the skin and lungs is increased, and the amount of urine is diminished. These are some of the immediate effects. Protracted residence in such a high region enlarges the chest capacity. The Quichua Indians, who dwell on the elevated table lands of Peru, have enormous-sized chests, containing capacious lungs with large air cells. The Mexican Indians possess chests which are out of proportion to the sizes of the individuals. Dr. Denison says that children born in the Rocky Mountains have chests of unusually large capacity, and M. Jaccoud states that at St. Moritz the respirations are not only more frequent, but fuller.

The reason why the number of respirations increases while ascending a high elevation becomes clear when we take into consideration the fact that at the sea level a cubic foot of dry air contains about 130 grains of oxygen, while at an elevation of 6000 feet it only contains about 106 grains—nearly twenty-five per cent. less than the body is accustomed to breathe at or near the seaboard—therefore, in order to supply the wanted amount of oxygen to the body, the respirations must either increase in number or in extent. From all accounts it is very probable that respiration becomes accelerated only during the early period of exposure to such an attenuated atmosphere, and that subsequently this function becomes slow again because the air penetrates more deeply and completely into lung tissue but little utilized before.

That man does not suffer under such a deprivation of oxygen is evident from what we know to be true of his lung capacity under ordinary conditions of life. Prof. Mosso has recently proven experimentally that man possesses a lung capacity which is nearly one-fourth larger than the actual necessities of life at the sea level demand; hence by employing his whole lung capacity he can extract a sufficient amount of oxygen from this attenuated atmosphere without difficulty. And herein lies the secret why so many consumptives, and others with weak lungs, derive such a great benefit when they resort to a mountain climate. It may be trite, but it is nevertheless true, that all consumption practically begins at the lung apices, because these parts are habitually inactive. These are inactive because, in the first place, the bronchial tubes are so arranged that they conduct the air with greater facility to the base than to the apex of a lung, and, in the second place, because the lung is larger than necessary; hence the base, which is filled most readily, is filled first, and the apex, if at all, toward the end of inspiration. The apices, therefore, become the superfluous parts of the respiratory organs. It is quite different, however, when the body is immersed in a highly attenuated atmosphere. Every available space in the chest is now brought into requisition to furnish the needed amount of oxygen, the apices are called out of their lethargic state, and the alveoli are inflated, and if the infiltrated areas are not dispersed the surrounding alveoli are kept permeable, and so the disease is, at least, limited and called into abeyance.

This statement is corroborated by those who have had large experience in the climatic treatment of pulmonary consumption. Thus Ruedi reports[1] "that of 600 consumptives under his care at Davos, expansion of the thorax took place in no less than 584." Dr. Denison says[2] "the increased circumference of the chests of consumptives after undergoing the high-altitude treatment is shown in many of Prof. Weber's, as well as in my own cases." Dr. Lindsay, in the work already quoted, states (p. 32) that "Davos does not cure consumption by its sunshine, or the purity and dryness of its air (although these conditions undoubtedly co-operate in the beneficial effect) but mainly by the rarefaction of its air, which stimulates respiratory activity, promotes healthy expansion and soundness of tissue in the lungs, and hence aids them to resist the spread of morbid deposits." So much, then, for the immunity which is afforded by mountain climates; but that which is of still greater interest to us is the fact that those who follow active employment are less liable to this disease than those who pursue sedentary and quiet occupations. Thus M. Lombard found "In Paris, Geneva, Vienna and Hamburg, that there are a greater number of persons leading a sedentary life afflicted with phthisis than of those leading an active life, in the proportion of 141 to 89. In the Brompton Hospital the relative liability was

[1] Climatic Treatment of Consumption. By Dr. J. A. Lindsay, p. 62.

[2] Rocky Mountain Health Resorts, p. 85.

found to be 63 per cent. of indoor males to 30 per cent. of outdoor, and all the consumptive females followed indoor occupations. Dr. Guy found in the close workshops of a printing establishment the compositors, whose employment is sedentary, fell victims to phthisis in the proportion of 44 per cent. to 31½ per cent. of the pressmen, who, although breathing the same air, and in every other respect subject to the same habits of life, differ only in the active bodily exercise which the press imposes on them; and among the same class of operatives the deaths from the same cause did not exceed 25 per cent. in those who use exercise in the open air." (Ancell.)

There can be no doubt, too, that those of our Indians who are still allowed to obey their roaming instincts of hunting and of fishing, or to follow their vocation of farming, which a number have, owe their immunity from this disease, which we know they possess, in great part, if not entirely, to the physical exercise which they obtain in this manner; while those who are subjected to the idle and improvident reservation life die rapidly from it, principally because they are deprived of their wonted exercise. This is of special interest to us here, because it has such a direct bearing on the main point at issue. Some of the former class of Indians, like the Pimas, for example, who may be called wild, although they are agricultural in their habits, are living in half underground huts, with very little or no ventilation, yet, from all accounts, consumption is an exceedingly rare disease among them.

Thus far we have seen that, on the whole, those who occupy elevated habitations, as well as those who follow active exercise, are more exempt from the disease under consideration than those who live near the sea level, or those who live a life of quietude. In connection with this we will consider the influence of physical exercise on the lungs, and endeavor to ascertain how it affords protection against consumption. During physical exercise more oxygen is consumed by the muscles, and more blood and air circulate through the lungs than during rest. Just how much more air enters the lungs during activity than during rest can easily be estimated when it is known that during inactivity a man breathes 480 cubic inches of air per minute, and while walking at the rate of four miles per hour, or while tramping a treadmill, he breathes 2400 cubic inches, and if he walks at the rate of six miles an hour he takes in 3260 cubic inches of air per minute. The difference between 480 and 2400 cubic inches of air capacity shows that during the exercise of walking even at the rate of four miles per hour, five times more lung service is thrown into action than during rest; which proves very conclusively that bodily activity possesses a marked influence in determining the degree of lung expansion, and that under such conditions regions of lung will be called into service which are never fully reached by air during bodily rest. This is in entire accord with what practically exists. Thus Darwin[1] says that the lungs in improved breeds of cattle, which naturally take very little exercise and are domiciled much of the time, "are found to be considerably reduced in size when compared with those possessed by animals having perfect liberty," and Waldenburg[2] states that the vital lung capacity is smallest in persons who lead sedentary lives, such as professional men, students, clerks, etc., and is greatest in those who follow active out-door occupations, such as sailors, recruits, etc. Chassagne and Dally, in their joint work on the *Influence of Gymnastics on the Development of Man*, report that at the Military School of Gymnastics of Joinville-le-Pont, out of four hundred and one individuals subjected to gymnastic exercises for five months, three hundred and seven, or seventy-six per cent., showed an increase of an average of two and one-half centimetres in the mammary circumference of the thorax. According to Dr. Abel, seventy-five per cent. of those who practice gymnastics in Germany experience an increase in the measurements of the chest. There can be no doubt that the principal reason why consumption increases with the advent of civilization is that everything in civilized life tends to produce physical inertia in our bodies. Walking is substituted by riding in carriages and in cars; manual labor is in great part replaced by machinery; active out-door labor is supplemented by quiet indoor occupations; in fact, everything which tends to produce physical activity is exchanged for a life of ease and indolence. The American Indian, as has already been stated, is known to be comparatively free from the disease in his wild state, but as soon as he acquires the habits of and customs of civilized life he becomes its victim.

In converging the two lines of reasoning which have been thus far developed in this paper, it appears that the immunity from consumption which is established by residing in

[1] Animals and Plants, vol. ii., p. 361.

[2] Pneumatische Behandlung Respr u. Circul. Krankheiten, p 119.

a mountain climate, and by practising physical exercise, is chiefly brought about in the same manner, viz., by increasing the capacity of the chest. And from a practical point of view it is of some moment to know whether the former has more weight in bringing about such restoration than the latter—or, in other words, whether those who live in high altitudes continue to enjoy this exemption if they refrain from active physical exercise and take up a sedentary occupation in such regions. From recent inquiry into this subject we are inclined to believe, at least so far as the Rocky Mountains climate is concerned, that as soon as outdoor pursuits are exchanged for sedentary indoor occupations, consumption increases in frequency. It is, therefore, quite certain that physiological exercise plays a more important part in the problem of the prevention and cure of consumption than a residence in an elevated or mountain climate, however valuable the latter may be. We have, moreover, good reason for believing that the immunity which is established through physsical exercise is more permanent in character than that which is secured through residing in a mountain climate, for it is a common observation that consumptives flourish only in high altitudes so long as they remain; a protracted stay at the sea level is always regarded as perilous. Such consequences are in perfect harmony with what one would be led to apprehend from a knowledge of the physiological factors involved in the restoration of the patient. These factors are entirely local, and their influence does not extend very far beyond their immediate dominion. This objection does not hold good in regard to physical exercise. One thing may be said, however, in favor of mountain climate which is not true of physical exercise, viz., it produces its beneficial results without conscious effort on the part of the individual; therefore, when the remedy is viewed from a standpoint of ease and comfort, and not from one of permanence, the mountain climate is to be preferred.

In discussing the influence of mountain climate it must not be overlooked that, on account of its rarefaction, it increases the circulatory and cellular activity of the body, and in this way undoubtedly aids the process of nutrition; yet even this influence cannot be denied to physical exercise, although it is brought about in a more direct and positive manner. While increased chest capacity is, therefore, the great desideratum in preventing and treating consumption, we have the strongest evidence for believing that it is not so much a question of developing the base of the lungs as it is of expanding the apices. This is well shown by the fact that the civilized female, although she has on the whole much less chest capacity than the male, yet, owing to her increased costal expansion, which has been cultivated through the protracted influence of tight lacing, she is less liable to pulmonary consumption than the male.[1]

Pulmonary gymnastics.—Such, then, are the comparative effects of mountain climate and of physical exercise in the treatment of pulmonary consumption, and it now remains to be shown how the effects of the latter can be obtained without resorting to those of the former. Reference has already been made to the fact that muscular effort increases respiratory motion, and in taking up the question of pulmonary gymnastics it is not our purpose to discuss those exercises only which have a direct influence on the chest capacity, but also those which, through the body, have an indirect influence on the pulmonary organs. In all exercises it is very important that none should be carried to the extent of decided fatigue; and that, whenever possible, the body and head should be kept erect, the shoulders thrown back and the lungs thoroughly filled with each breath; that breathing should only take place through the nose; and that sufficient food is taken during the intervals.

Bodily exercise.—The power of walking is common to most people, and its influence on the lungs, as we have seen, is very marked. It is regarded of great service even by those who exclusively advocate the utility of high altitude treatment. Dr. Brehmer, of Görbersdorf, according to Schreiber, was the first to prescribe, for consumtives, walking up a gradual ascent. A semi-daily walk of half an hour or an hour, either on the level or on a slight upgrade, is of immense advantage to the invalid. Running, dancing, skipping rope (especially when the rope is swung backward), bowling, etc., are to be highly recommended. Whatever the mode of exercise may be, it must be performed under as little compulsion as possible. One reason why the above named exercises are so conducive to health consists in the fact that the excitement which they induce is so attractive that the consciousness of muscular effort is lost.

Among the many indoor exercises the following movements are very valuable. The arms being used as levers, are swung back-

[1] Female Dress as a Determining Factor in Pulmonary Consumption. Thomas J. Mays: *Medical News*, Jan. 7, 1888.

ward as far as possible on a level with the shoulders during each inspiration, and brought together in front on the same level during each expiration. Or the hands are brought together above the head while inspiring, and gradually brought down alongside the body while expiring. When a deep inspiration is taken is accordance with either plan and held until the arms are gradually moved forward or downward, or even longer, the process of chest expansion is materially enhanced. Another very effective exercise is to take a deep inspiration, and during expiration only the patient, in a loud voice, will count as long as possible. A male person with a good chest capacity can count up to sixty or seventy, while in a female with ordinary lungs this power is somewhat reduced. Practice of this sort will gradually develop the chest, and the increased ability to count is a measure of improvement going on within the thorax. Many of these movements may have their effects greatly enhanced by the use of dumb-bells, chest weights, etc., which are made especially for the purpose.

Compressed and rarefied air.—The breathing of compressed and rarefied air is attracting wide attention at the present time in connection with pulmonary consumption, and is another most useful method whereby the chest capacity can be markedly improved. Nearly four years ago Dr. Cohen, the honored President of our Society, advocated the substitution of compressed and rarefied air for a change of climate, in a paper which he read before the American Climatological Association. Here he says:

"In many cases fully as much good can be secured by this treatment as by change of climate, and in a few much more; though, in the vast majority of cases in which change of climate is advisible, it is but a poor substitute."

There can be no doubt that compressed and rarefied air is inadequate when used alone in many cases, but when combined with pulmonary gymnastics and other judicious treatment, we are not sure that the results obtained are inferior to those which are derived from climatic treatment. Recent experience has shown us that when consumptives, who had spent one or two winters on the Rocky mountains, or on the Pacific slope, without benefit, were subjected to the use of compressed and rarefied air in association with other pulmonary exercises, such as are above described, their improvement became marked and decided. On the whole, our experience with the air treatment, combined with pulmonary gymnastics, has been very favorable, and we think that this is in consonance with the observations of others. Thus the late Prof. Flint, in his work on "Phthisis," says (p. 406) "it does not appear, from the analysis of my cases, that changes of climate have in a marked degree a beneficial influence, as compared with the hygienic measures available at home."

We believe, however, that, as a rule, these measures are applied too infrequently to be of the greatest service; and therefore, insist that the pulmonary gymnastics are repeated every hour and a half during the day—the first thing in the morning and the last thing at night—and for from fifteen to twenty minutes at each time; and that the air inhalations be given at first twice, and in the course of two or three weeks gradually increased to four or five times a day, and even oftener. It is very true that this method of treatment involves more labor and perseverance on the part of the patient than is required in a high mountain climate; but then it is a question whether the patient is not more than compensated by the consciousness that a separation from friends is unnecessary, that the heavy expense, the dangers and discomforts incidental to travel are avoided, and, above all, that the improvement which may take place will be persistent and be practically unaffected by a change of residence.

Now, after reviewing the whole subject, we are driven to the conclusion that the line of immunity from consumption, which, in the early history of our country, was located at the Atlantic seaboard, and which has gradually receded westward with the tide of civilization, until at present it has reached the latitude of Colorado, will not stop in its course until it touches the shores of the Pacific; that the question of curing the disease does not depend on the purity or freshness of the air, or upon the number of bacilli which the atmosphere may contain, or upon the amount of oxygen which may be introduced into the body—for these are all secondary considerations; but it is simply a mechanical question—a question as to the best mode of expanding the lungs, and especially the apices of our round-shouldered and flat-chested patients, of removing the infiltrated products already existing, and of enhancing the constitutional resistance.

—On the 19th of February the cornerstone of a polyclinic was laid with appropriate ceremonies at Rome, Italy. Dr. Bacelli, professor at the medical clinic, delivered the address.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, February 27, 1888.

The President, Laurence Johnson, M.D., in the chair.

Dr. Charles W. Allen read the scientific paper of the evening, on

Leprosy in the United States, and its Relation to the State.

The history of leprosy in the United States was reviewed. The questions as to its hereditary and contagious nature and the necessity for segregation were discussed. Some years since leprosy appeared in South Carolina, and it has also appeared in Louisiana, and in more recent years in Iowa, Minnesota, Michigan, Wisconsin and Illinois, to which places it had been brought by immigrants; it is also present on the Pacific slope, being brought there by the Chinese. Some cases have appeared in the States bordering on Mexico, where it had been brought by those coming from the South. A few natives have acquired leprosy while visiting foreign lands, and there have been reported five cases among natives who had never been abroad.

The author continued the histories of some cases at the Charity Hospital, which had been first reported by Dr. Piffard in 1883, and also gave the histories of two other cases which had not yet been reported. One of the latter was presented to the Society. In this instance some disfiguring effects of the disease upon the eyebrows and face had led him to institute surgical interference for cosmetic reasons. The wounds had healed readily. Dr. Allen thought we might safely estimate the total number of lepers in this country at one hundred and fifty, and not count twice cases reported by different observers. Owing to the size and geographical location of the United States, he thought we were likely to have more and more cases visiting our country.

Dr. Allen, in discussing the hereditary and contagious nature of leprosy, gave the opinions of those physicians who had resided in countries where leprosy was common, and also the conclusions reached by the committee appointed to investigate the subject by the Royal College of Physicians of England, as well as the opinion of the majority of the members of the Academy of Medicine, Paris, which was in opposition to the view of contagion. The majority looked upon the disease as hereditary, but there was a growing number of believers in the contagious nature of the disease, and this belief had led in different countries to the segregation of lepers. Individual instances were given to show the contagious nature of the affection. Those looking for proof of its infectious nature often failed to consider that the period of incubation might be many months or several years. In view of the action of the Philadelphia Board of Health we should seriously consider, he said, whether or not the disease was sufficiently contagious to justify State regulation. Syphilis and tuberculosis were contagious diseases, but only slightly so, and they had come to be very prevalent. He might be asked, why not institute isolation of patients affected with the latter diseases? Dr. Allen said he would favor isolation if it could be shown that thereby those diseases could be stamped out. If there were danger of leprosy spreading in our country by contagion, he thought we should segregate the patients afflicted with the disease.

Referring briefly to treatment, he thought that it was beneficial, and mentioned the value of chaulmugra oil.

Dr. H. G. Fox opened the discussion, and said that while he was not prepared to offer proof for his views, it was his opinion that leprosy was both contagious and transmissible by heredity. Although he believed it was contagious, it could be only very mildly so, and for that reason, and the further reason that our conditions were different from those of people in leprous countries, he did not think the State would be justified in shutting the patients up, and excluding them from association with their fellow-men unless the latter were similarly affected with themselves. He did not look upon leprosy as an incurable disease. One case in which he had effected a cure, principally by chaulmugra oil, was that of a patient from whom he had recently received a letter, stating that there had been no return of his former symptoms. But if patients were deprived of their liberty, all hope being taken away, and were allowed to associate with none but those similarly afflicted, no kind of treatment would be likely to prove of much benefit.

Dr. P. A. Morrow also believed that leprosy was both contagious and transmissible by heredity; that it was a germ disease, although we know very little regarding the method in which the germs entered the sys-

tem and the conditions necessary for the development of the disease. While he believed leprosy was contagious, it was evident that it was only very mildly so, and he did not think there was any necessity for State regulation in this country. The disease as it prevailed in the Sandwich Islands should not be taken as a basis of comparison for its probable advance in this country. The conditions were entirely different. It seemed to be the common impression that in Norway the decrease in the number of cases was due to segregation; but this was a mistake, for the lepers there were not rigorously isolated; they were allowed to go out and see their friends.

Dr. D. B. DELAVAN thought some of our physicians took too optimistic a view of the question under discussion: the relation of leprosy to the State. We should ask ourselves three questions: First, was leprosy at all communicable; second, was it all times equally contagious; third, what had been the result of segregation? While it may not have been shown to be very contagious, yet its history in Europe during the middle ages afforded a very instructive chapter. It started at one corner, and rapidly spread its ravages through the whole of Europe. Could we be assured that such an epidemic would not occur again? Wherever leprosy had prevailed segregation had been found desirable. Comparing the disease with syphilis and tuberculosis, Dr. Delavan said that if these latter could be stamped out by isolating a dozen or more patients, we certainly would be justfied in that course; if leprosy could be prevented from any further spread in this country by isolating the few cases now present, he thought the State would be justified in exercising such sanitary police regulation. Dr. Delavan also spoke of the beneficial results from the use of chaulmugra oil.

Dr. KOPLIK said the question had occurred to him, Might not opening up the lymph channels in a surgical operation for cosmetic effects, as was done by Dr. Allen, be followed by more rapid progress of the disease?

The following resolution, framed by the Georgia Medical Society, was adopted: Resolved, that we urge upon Congress that, in the cause of humanity, the import duty should be removed from all medicines, medical and surgical appliances, and from everything used in the treatment and diagnosis of disease.

—J. H. Walsh, the editor of the English sporting journal *Field*, died Feb. 12. He was a physician and practiced medicine for some years. He is the author of "British Rural Sports."

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, February 22, 1888.

Dr. W. W. KEEN in the chair.

Dr. THOMAS J. MAYS read a paper on

Apex Expansion versus Pure Air in Pulmonary Consumption.

In opening the discussion on Dr. May's paper[1] Dr. W. W. KEEN said: These are very practical questions presented for discussion. Change of climate involves expense, separation from friends, interruption of employment. Can we obtain equal benefits by home gymnastics or change of employment? There is also a novel question raised as to purity of air. These points should be discussed.

Dr. WILLIAM OSLER said: The last statement of the paper contains a very important truth. With imperfect expansion there is a liability to clogging of the interstitial circulation in the apices and accumulation of tissue *débris* which may afford a nidus for the development of the bacillus tuberculosis. The condition of activity of this interstitial circulation differs very much in different individuals. We know but little yet of the conditions which determine the development of tuberculosis. In part, at least, it is like the old parable of the seed and the sower: the nature of the soil will favor, retard, or prevent the growth. That the bacillus of tubercle will not grow in every soil is demonstrated by autopsies in large general hospitals. At Blockley, we will find in every hundred sections, say, fifteen or twenty cases with the usual lesions of phthisis; in fifteen or twenty there are no excavations, the lung not extensively tuberculous, but at the apices are small areas of induration, caseous nodules, and a few peripheral miliary nodules. The soil has not been congenial, and the development of the bacillus was restricted. Without bacillus, no tuberculosis; and that opinion is shared by ninety-nine out of every hundred clinicians of the day.

Dr. EDWARD MARTIN said: While connected with the department of physical education at the University of Pennsylvania, I had an opportunity of studying the effect of exercise on chest development. Lads admitted with narrow lungs and supraclavicular depressions suffer, after moderate exertion, with embarrassment of pulmonary circulation. The right heart is congested, and there is evidently blocking of the blood cur-

[1] See page 295.

rent in the lungs. After six or eight months of carefully regulated exercise, there is a change in the local condition; no more obstruction is offered to the right side of the heart than elsewhere; the blood-vessels respond to the extra demand put upon them. With this free circulation goes an increase of chest girth, from an inch to two or two and a half inches in six months. Inspiratory exercises are nearly always given these young men, especially those with that shape of chest which we are taught predisposes to phthisis. Among these exercises is prescribed deep breathing, with or without movement of the arms. The arm is raised from the body to a right angle by the deltoid. After that the lifting is done by the serratus magnus, the most important external inspiratory muscle. As the arm is carried nearer to the head, the insertion and origin of the serratus are approximated and the muscle works at a disadvantage. For this reason expiration is practised as the arms are carried up, and inspiration as they are brought down. Exercise should be made vigorous enough to stimulate the heart action. Slow motions, as a rule, do not strengthen the heart muscle, but have a local effect, whereas the object in these cases is to make the circulation free and the air tubes pervious.

Dr. C. W. Dulles said: Dr. Mays has done good service by calling attention to the fact that the conditions to secure which consumptives are recommended to live at high altitudes can be replaced by simple measures. My observation, though limited, corresponds with that of Dr. Mays, and I think that all of us have been struck with the fact that there is no direct ratio between the percentage of cases of phthisis and the breathing of impure air. We often see a number of persons huddled into small, unventilated rooms, with filth and drink and all the factors of disease, and yet apparently in blooming health. In such cases the men, who are engaged in active employment, and the children, who run about in the streets, enjoy better health than the women, who have less active exercise and who bend over washtubs or sewing work.

Dr. George E. Shoemaker said: I heartily agree with Dr. Mays that apex expansion is an important part of the treatment of incipient lung disease. A very important point is raised as to the action of rarefied air in expanding the apices. In localities that are warm, moist, and low—like Florida, for example—there is no such effect, and almost the sole benefit, as far as the climate is concerned, is from the patient's ability to be outside all the time. Now would it not be better to send more of our patients to a climate where direct good is gained by the more thorough ventilation of the lungs, reserving for Florida the very weak and those liable to excessive hemorrhage or to heart failure? In regard to impure air, we must remember that many of those persons who enjoy good health in spite of their home surroundings, live out of door most of the time, the children, in particular, living upon the doorstep or in the street, except in stormy weather. In the same way at mountain and seaside resorts, the small and uncomfortable rooms drive visitors out into the air; and whether or not ozonized or rarefied, it is pure, out-of-door air.

Dr. Mays said, in closing the discussion: It is rather unfortunate that Dr. Osler did not confine himself to the topic of the paper and discuss the main points of the subject in his usual able manner. I purposely avoided all except an incidental reference to the bacillus; but I must now say that I cannot accept the dictum, "no bacillus, no tuberculosis." It seems very strange that if the bacilli need a soil in which to develop they should be able to penetrate into that portion of the lung which is hardly ever expanded in phthisical patients. Why, if you take the two sexes and put them side by side in the same employment, do the men become diseased in greater proportion than the women? Why this fondness of the bacilli for one sex? I must also dispute the point that ninety-nine of every hundred clinicians accept this dogma. Though born in Germany, the doctrine is already losing ground among the Germans. I wish, in conclusion, to make a statement which I should have embodied in the paper, that, according to the latest researches, the apices expand more in the recumbent than in the erect position; therefore, a person inhales more air during sleep than in waking hours.

—Admiral Hutton Versturme, who retired from the British navy about a year ago, and lived near Falmouth, Eng., recently committed suicide. He was found in the drawing-room in front of the fireplace suffering great agony, with his wife also in the room insensible. A doctor found that he had thrust into his stomach a thin brass-handled poker, red hot, inflicting three severe wounds. He died the next day. He spoke several times, once saying, "It was because of the whiskey I did it." He was much distressed through not coming into a fortune that he had expected on the death of a relative.

Reports of Clinics.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

MEDICAL CLINIC—PROF. PEPPER.

Circumscribed Pleuritic, Simulating a Pericardial Effusion.

William B., aged 68. This old man was admitted to the wards about six weeks ago. The prominent symptoms from which he was suffering at that time was an urgent dyspnœa, and, what was remarkable in the case, there was no discoverable cause sufficient to account for it. The heart, for a man of his age, was quite normal; no organic lesion was present, and the pulse was regular and fairly strong. The kidneys were searched for some evidence of Bright's disease, which would offer an obstructed circulation as a partial explanation of the dyspnœa, but without success. Repeated examinations of the urine proved entirely negative. There was a slight cough present, but the lungs on being examined, were found to be quite healthy with this exception: at the right base posteriorly a small patch could be outlined, over which numerous small râles were heard. Some infiltration was present here, but no solidification. Bacilli were looked for in the sputa, but none were found. The patient was rather anæmic, and there was some slight febrile disturbance. This was all. Certainly there was nothing in these insignificant data to explain the markedly oppressed respiration. The man was placed upon a tentative plan of treatment and kept under close observation. As time passed, the area of infiltration at the base of the right lung increased in extent and spread upwards as high as the lower angle of the scapula. At the same time, the dyspnœa became even more harassing so that the patient was almost gasping for breath. As these conditions gradually acquired greater prominence, it was noticed that the area of cardiac dullness was extending; that there was a palpably increased fullness of the precordia, and that the heart-sounds were receding. A week ago the cardiac dulness extended, vertically, from the second to the sixth rib; horizontally, from the right border of the sternum to a point an inch outside the nipple line. The heart's impulse became almost imperceptible and its sounds could only be distinguished at the base. With all this, gentlemen, I venture to recall your attention to the fact that, on admission, the patient presented no evidence of any organic lesion of the heart.

Now what was the morbid condition here that we were called upon to treat? There was undoubtedly a large quantity of new material in the thoracic cavity, but was it solid or fluid, and what was the connection between it and the pulmonary lesion on the right side? The possibility of neoplasm, malignant or benign, was first considered. The evidence furnished by physical examination, however, was all against the adoption of such a view. Neither lung was displaced to any extent, nor was there marked dulness over them at any point; the position of the heart was not materially altered, its sounds and impulse being rendered indistinct by this new growth or effusion gradually surrounding it rather than pushing it aside. A solid body, moreover, would not have exhibited such rapid increase as was obtained here.

We had, therefore, to deal with a fluid, an effusion, and, in the entire absence of anything pointing to the existence of pus, a serous effusion. To verify this conclusion the needle of a hypodermic syringe was inserted just outside of the apex line of the heart and a drachm of serous fluid drawn off. Having in this way satisfactorily disposed of this first question, a second now presented itself for solution. Was this a collection of fluid within the pericardial sac or was it a circumscribed effusion into the left pleural cavity? It will be remembered that at the time of the patient's admission, the difficulty of breathing was most urgent, and yet careful examination of the heart at that time failed to reveal the presence of an abnormal amount of fluid within its enveloping membrane. The cause of the dyspnœa, therefore, was exo-cardial, and while this symptom steadily increased in severity, it was not until the man had been under close observation for some days, that the bulging of the intercostal spaces was noted, and the impulse and sounds of the heart began to grow fainter. From a careful review of this array of facts, we are led to believe that the effusion is pleuritic in origin, and that it is limited by old adhesions to the inner portion of the pleural cavity extending forwards to the anterior border of the lung and overlapping the heart. It is probably dependent upon a sub-acute inflammatory process, the exciting cause of which we do not know.

A week ago the needle of an aspirator was introduced into this distended cavity and thirty-six ounces of a clear serous fluid drawn off, the resulting relief to the patient being, as you may imagine, very great. My examination to-day shows that there is some re-accumulation of the serum, and I think it

likely that the tapping will again become necessary.

Before dismissing this case I wish to say one word with regard to exploratory punctures of the pericardial sac. When it is desirable that one of these shall be made, the point always selected by me for the insertion of the needle is the normal site of the apex beat of the heart. I puncture here because it is at this point that there is the least danger of wounding that organ. If any pericardial effusion occurs, even though it be slight, the apex of the heart being its most freely movable portion, is early displaced and pushed up of harm's way.

General Tuberculosis.

Harry S., 4 years old, youngest of eight children, the eldest of whom died a year or two ago of phthisis. The mother a healthy woman, but the father syphilitic. The child began ailing early in December last. The bowels became irregular in their action, constipation alternating with diarrhœa; colic was of frequent occurrence, the appetite became capricious, the stomach irritable, and vomiting easily induced. Irregular febrile disturbance, restlessness, and broken sleep became prominent symptoms, and the child underwent rapid emaciation. Examination reveals the following conditions: At the upper part of the abdomen, just below the border of the diaphragm, we find a network of dilated veins, these indicating the existence of some obstruction to the intra-abdominal circulation. There is no fluid of consequence in the belly, but on palpation it is found to have a doughy, inelastic feel, and is somewhat resistant to pressure. Passing upwards to the contents of the thoracic cavity, we find the entire right lung a mass of infiltration, tubercular deposits being disseminated throughout its whole structure, with commencing softening under the clavicle. There is, in addition, internal strabismus of the left eye which is strongly suggestive of tuberculosis of the cerebrum or meningeal membranes. To sum up, therefore, we have first extensive tuberculization of the peritoneum and intestines; next, a widely disseminated tuberculosis of the right lung; and, finally, a well-grounded belief as to the existence of intracranial tubercular deposits. Such general tuberculosis as this is rare in so young a child, and is particularly remarkable in this case because the first symtoms of disease were observed scarcely more than two months ago.

The treatment of such a case can, of course, be simply palliative. The most sanguine of therapeutists could not hope to effect a favorable issue. Elevation of temperature will be kept within bounds by moderate doses of antipyrine, and pain and diarrhœa controlled by opium. As other symptoms arise or occasion distress they will receive attention, but these are at present the leading indications.

Foreign Correspondence.

LETTER FROM CANTON, CHINA.

It may interest the readers of the Reporter to hear and learn something of medical work in the far East, and of what the Canton Medical Missionary Hospital is doing for the Chinese. Fifty-two years ago this hospital began its work of benevolence in this great city which has a population of a million and a half. At first under the care of Dr. Peter Parker and others, it has for the past thirty-one years been nearly all the time under the care of Dr. J. G. Kerr, by whose skillful management and untiring devotion it has risen to one of the largest (if not the largest) hospital in the East, and with a reputation among the Chinese reaching all over this vast empire. It is impossible to get an adequate idea of the large amount of work done and good accomplished at this hospital year after year.

There are two departments, one for men and one for women, and at present two hundred and fifty in-patients can be accommodated. During some of the summer months every ward is crowded to its utmost capacity. While many cases coming under the class of general diseases are admitted, yet the work so far as in-patients are concerned is largely of a surgical nature. These include all affections that fall to the surgeon's lot at home, specially prominent among which are: urinary calculus; tumors, both malignant and non-malignant, including all varieties of cancer; caries and necrosis; cataract, etc. Two wards are devoted to cases of urinary calculus, and during most of the time there are from ten to fifteen of these patients present, either under preparatory treatment or already operated upon. During the past three years (Jan. 1, 1885, to Jan. 1, 1888) there were one hundred and twenty operations of lithotomy, and thirty-three lithotrity operations performed; the age of the patients ranging anywhere from one year to seventy-five years. Dr. Kerr has performed hundreds of these operations, and with reference to numbers and good results in this disease he probably stands as one of the first surgeons in the world.

Two days of the week are devoted to seeing out-patients who come in great numbers, as will be seen by the summary given below. Well trained native assistants do much of the routine work, and a medical class of young men receive regular instruction. Calls are frequently made to see patients who are unable to come to the hospital, and many of these are obstetrical cases.

A summary of the work for 1886 is as follows:

Number of out-patients,	13,000.
" " in-patients,	1,300.
" " operations performed,	2,200.

It is impossible at present to go into details, or report any of the rare and interesting cases that are constantly occurring in our practice.

Dr. Kerr is at present assisted by Miss Mary W. Niles, M.D., and the writer of this article; but until within a few years he has carried on this great work alone, living in this tropical climate, in a heathen city, hidden from the world and society, devoting his life to the relief of his fellow-men and the service of the Great Physician, for the advancement of whose cause he labors.

The influence of this hospital for good is far-reaching and untold. During the year 1885 there were patients from every province in the Chinese empire, except one, and from Manchuria beyond the northern border. Native students have gone forth to hold important positions. Instruction in the Christian religion is always a prominent feature in connection with the work. Numerous medical works, translated by Dr. Kerr, are known and in use wherever Western medical science is taught to the Chinese.

May the day be soon forthcoming when the medical profession in general will carefully inquire into the subject of medical missions learn what they are doing and of the great work yet to be accomplished by them.

Yours truly,

JOHN M. SWAN, M.D.

Canton Hospital, Canton, China,
January 14, 1888.

—The *Boston Med. and Surg. Journal*, Feb. 16, 1888, states that it appears from the annual report of the Harvard Medical School, 1886–1887, that not one-half of those who take the fourth year course apply for the fourth year degree. During the past four years 35 per cent. of the candidates for the fourth year degree have been rejected. The number at present in the fourth year class is stated to be 10.

PERISCOPE.

Microbes and Expired Air.

Strauss and Dubreuih (*Concours Médical*, No. 50, p. 601, 1887) have recently made extensive experiments, and working in a different manner have confirmed early results of Tyndall's, showing expired air to be entirely free from germs. Their method was to pass the air through tubes containing sterilized nutrient solutions, using about one hundred and fifty to two hundred liters of air for each tube. Almost without exception the tubes remained sterile, and the number that did not, could be accounted for by errors of manipulation. These experiments show that the lungs act as filters to the inspired air, an action easily explained by the conditions under which air circulates in the lungs, through narrow channels lined with moist epithelium. Grancher, Charrin and Karth, have already shown the air expired by phthisical patients to be free from the pathogenic bacillus. There is no contradiction between these facts and those long ago observed by Pasteur, and confirmed by many since then, showing the abundance of germs in hospital wards, barracks and other crowded apartments. It is not by the respiration that crowds charge the air with microbes. This is done by means of clothing, by the dust set in motion by their movements, and by dried and pulverized expectoration.

Quarantining School-Children after having Contagious Diseases.

The Section of Hygiene of the Academy of Medicine of Paris has recently reported to the Academy some suggestions as to the duration of quarantine to be imposed on school-children who have suffered with a contagious disease, among which whooping-cough is now classed in addition to the diseases named in the report of 1881. The present report was made to the section on hygiene by M. Ollivier. From the *Bulletin de l'Académie de Médecine*, Jan. 24, 1888, we quote the following suggestions:

1. Pupils attacked with chicken-pox, small-pox, scarlet-fever, measles, mumps, diphtheria, or whooping-cough shall be strictly isolated.

2. The duration of this isolation shall be reckoned from the onset of the disease—the first day of invasion; it will last forty days for small-pox, scarlet-fever and diphtheria; twenty-five days for chicken-pox, measles, and mumps. As the duration of whooping-cough is extremely variable, a return to school

should not be authorized until thirty days have elapsed after complete disappearance of the characteristic fits of coughing.

3. Isolation shall cease only when the convalescent shall have taken two or three soap-baths, and have been submitted to an equal number of general frictions, even of the hairy parts of the skin.

4. The clothing which the pupil had at the time when he was taken sick should be subjected to the action of steam under pressure or to the action of sulphur fumes, and then well cleaned.

5. The room which has been occupied by the patient should be well aired. Its walls and furniture shall be thoroughly disinfected; the bedding shall be subjected to the action of steam under pressure; and finally, the mattress shall be taken apart and submitted to the same treatment.

6. In any case the pupil, who shall have been attacked outside of a public school with one of the contagious diseases enumerated in this report, shall be received again only when provided with a certificate from the physician stating the nature of the disease and the time which has since elapsed, and attesting that the pupil has fulfilled the above requirements. Finally, the reception of the pupil shall always be subject to the results of an examination by the physician to the school.

Bacteriological Water-Test.

At the meeting of the Society of Medical Officers of Health (*Brit. Med. Journal*, Jan. 7, 1888), Mr. Gustav Bischof read a paper on extension of time of culture in Dr. R. Koch's bacteriological water-test by partial sterilization, with special reference to the metropolitan water supply. The following conclusions were drawn: 1. No bacteriological water-test can satisfy the demands of hygiene unless it is qualitative, distinguishing between harmless and pathogenic microphytes. No such test is at present known. 2. Merely numerical results, without such distinction, are entirely unintelligible, unless the time and other conditions of culture of each test is specified. 3. A small portion only of the colonies capable of growing in gelatine peptone is indicated by three days' culture. 4. The ratio of colonies thus indicated by three days' culture to that of the total present appears to differ so widely in different samples that the numbers of colonies obtained from them cannot be compared with each other. 5. Instead of any such comparison, the changes taking place from time to time should be followed up in each sample separately. 6. Extension of culture beyond three days increases the reliability of the results. How far this holds good, and how far culture should be extended, we have at present not sufficient evidence to show. 7. The usefulness of results is probably still further increased by combination of extension of culture with storage in sterilized flasks for a certain time. 8. As regards the control of the working of sand filtration at waterworks, any bacteriological test, to be of practical utility, should be repeated at intervals certainly not exceeding a fortnight. 9. It is desirable for the purpose of such control to test the water entering and leaving each filter.

Aprosexia.

"Aprosexia," a word clear to the Greeks, is the name of a new disease discovered by Guye, of Amsterdam. He understands by it a specific disturbance of the functions of the brain, appearing in the form of an inability to direct the attention to a particular subject. The well-known nasal reflex, the scapegoat of many who cannot explain a phenomenon, is brought forward again in this disease: aprosexia is a condition of exhaustion in consequence of difficult breathing in nasal diseases; certain cases of "overwork" belong to it.

As put by the critic in the *Berliner klin. Wochenschrift*, Dec. 5, 1887: "if Guye is correct, the future 'school-doctor' will have to examine the noses of scholars on the rear benches most thoroughly."

Dysentery with Gangrene of the Left Foot.

At a meeting of the Royal Academy of Medicine in Ireland, December 2, 1887, (*Lancet*, January 28, 1888), Dr. W. G. Smith reported the case of a young woman, 19 years old, who was admitted into the hospital September 2, 1887, suffering from intractable diarrhœa of a week's duration. Her illness had commenced suddenly, and followed the eating of some stale fish. When admitted she was in a state of extreme prostration; pulse 120, temperature 99.5°; frequent dysenteric stools. No treatment proved of any avail, and she died after a week's stay in hospital. Two or three days after admission her left leg was observed to be very cold. It was also painful, especially in the popliteal space, and purple patches appeared on the foot. These latter increased and deepened. Dry gangrene attacked the toes, and spread over the sole of the foot. At the autopsy, characteristic signs of dysentery were found, but no vascular obstruction to account for the gangrene.

Acute intestinal Obstruction; Laparotomy; Recovery.

The *Lancet*, January 7, 1888, reports the case of a man, 45 years old, a laborer, who was admitted on April 30, 1887, to St. Bartholomew's Hospital, under the care of Mr. Morrant Baker. The patient gave a history of double, reducible inguinal herniæ, of many years duration. A truss had been worn during the previous eight years. He had also a small reducible umbilical hernia. The patient had been quite well up to the morning of April 25 (five days before admission), when, after working about half an hour, he was suddenly seized with severe abdominal pain, which was referred to the umbilicus, and thence downwards to the right side of the pubes. The pain was of a dragging character, and thinking that it might be due to the hernia on that side not being quite all reduced, he lay on his back and re-adjusted his truss, but without relief. The pain continued all that day and the next, but he still remained at work, and vomited a little on both days. On April 27, the pain was worse, and the vomiting more frequent. On the 28th and 29th the pain and vomiting had increased. On the day of admission (30th) the patient was much worse and very weak, the pain being intense, and he had vomited at least twenty times in the twenty-four hours.

On admission, he was much collapsed, with all the symptoms of acute intestinal obstruction. The abdomen was somewhat distended, and acute pain was complained of, extending from the umbilicus to the right side of the pubes. The tongue was thickly furred and dry; the pulse 84, and weak; the temperature 99.6° F. There was frequent vomiting of a foul-smelling, green liquid. The patient did not remember having passed flatus after the onset of the pain.

After chloroforming him, the herniæ were carefully examined, and found to be easily and completely reducible. The abdomen was therefore opened, and on the right side was found a sense of resistence as though "the coils of intestine were tethered in some abnormal way." In endeavoring to find the cause for this, and in making some traction on the tense bowel, the coil suddenly came into view, and presented to the eye at once an intensely inflamed spot of about the size of a florin with dusky centre. The inflamed surface was rough, as if it had been firmly adherent and tightly gripped. The piece of intestine was immediately returned and the abdominal wound stitched up in the usual way. The patient was immediately relieved by the operation, and convalesced rapidly.

The author in commenting on this case, expresses the opinion that it was one of strangulated obturator hernia. This, he thinks, is indicated by the fact that other herniæ existed. At all events, he regards it as a case of intestinal obstruction which would have proved fatal without operation.

Mental Disorder Caused by Jaborandi.

Dr. Wauzh, of Liège, who has great belief in the efficacy of jaborandi as a stimulant of the mammary functions, mentions a case which has recently occurred in his practice, showing that inconveniences may occasionally arise from the administration of this drug. He prescribed ten drops of the fluid extract every four hours for a patient whose milk had ceased for a fortnight, with satisfactory results, the secretion being re-established. After a time, however, the patient began to suffer from extreme nervous excitement, accompanied by a fixed idea that she should murder all her family with a hatchet. On the jaborandi being stopped, these alarming symptoms disappeared, and together with them the activity of the mammary glands.—*Lancet*, December 24, 1887.

Primary Inflammation of the Internal Ear.

G. Gradenigo contributes to the *Arch. für Orenheilkunde*, xxvi, S. 46, the result of an anatomico-pathological investigation upon the organs of hearing of a deaf-mute girl, fifteen years old, who died of pulmonary phthisis. Anatomical information with reference to the primary affection of the ear was wanting. The autopsy disclosed bilateral complete destruction of the membranous labyrinth, and of the elements of both windows of the labyrinth; and new formation of fibrous and bony tissue, which appeared especially pronounced on the left side, where there was, in addition, a chronic suppurative inflammation of the middle ear. The newly-formed bone tissue is derived partly from the endostium of the labyrinth—periosteal bone, which is present only in the vestibule and gyrus basilaris cochleæ; and partly from direct proliferation of newly-formed fibrous tisssue — especially in the cochlea bordering on the modiolus. There was no trace of the semicircular canals; the vestibule was decidedly narrowed; and in the cochlea the new-formed bony tissue diminished as the apex was approached.—*Centralblatt f. d. med. Wissensch.*, Dec. 10, 1887.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE ABUSE OF ALCOHOLIC BEVERAGES.

Among the many interesting and important subjects discussed at the recent Hygienic Congress in Vienna, none was more interesting or more important than that of the abuse of alcohol as a beverage, and the means for correcting this abuse. The discussion which took place at the Congress has been followed by an equally interesting one by the members of the German Society of Public Hygiene, which is reported in the *Deutsche Medizinal-Zeitung*, Feb. 6, 1887, and in which a number of men who had attended the Congress took part. At this meeting, SPINOLA made an address, in which he described the great increase of liquor-drinking in civilized countries during the last few decades, and attributed this increase largely to the cheapness of strong alcoholic beverages, and the multiplication of what are called in this country drinking saloons. To this statement of the causes of the increase in the consumption of alcoholic liquors, he added some suggestions in regard to the best way to correct the abuse, which may well be reproduced.

These suggestions include action by governments and action by citizens banded together in voluntary organizations. The duty of governments consists in regulating the liquor-traffic, by imposing taxes, so arranged that they will make strong alcoholic beverages comparatively costly, and mild alcoholic beverages comparatively cheap. Further, governments should restrict the number of places in which alcoholic beverages are sold; should subject them to close supervision, and regulate the quality of liquors sold, as well as the methods of dispensing them. It was further suggested that governments should exercise a strict supervision over persons addicted to the abuse of alcoholic beverages, confining them when they become public nuisances, or when they neglect to support themselves or those naturally dependent upon them.

The duty of citizens, as citizens, was defined by Spinola as consisting in supporting the government in its efforts to lessen the evil of intemperance, and in organizing to promote temperance—or total abstinence, if that be preferred—and in furnishing the poor with sound teaching, good food, non-intoxicating beverages, and rational forms of amusement.

To the support of these opinions, which were those of the Vienna Congress, as well as his own, Spinola brings an array of statistics which is of the greatest value. It seems clear from them that the abuse of alcoholic beverages is actually the great evil which most independent observers believe it to be, and that the methods he suggests are well calculated to correct it. We have no space in which to reproduce the details of his statistics; but we think it worth while to call attention to the plan which has worked so well in Norway and Sweden, where the so-called Gothenburg system is in force. The essential features of this system are that a responsible society purchases the right to sell liquors, and that the profits are used to pay interest upon the capital of the Society, and the excess above this interest is devoted to public and charitable uses. A detail of the system, which is not without influence in

diminishing the abuse of alcoholic beverages, consists in the fact that the keepers of drinking-places may not sell alcoholic beverages for their individual account; but may so sell non-alcoholic beverages and articles of food. This gives them a direct interest in diminishing the use of alcohol, and encouraging that of articles of food and drink which contain no alcohol. As a result of these measures, and of careful supervision by the government, the average consumption of strong drink in Norway, which was fifty-four liters *per capita* annually fifty years ago, is now only eight liters, or about one-seventh of the former figure.

The facts stated above are of great interest to the citizens of this country, in connection with the efforts now being made to correct the abuse of alcoholic beverages which afflicts the United States. We have, from time to time, published information in regard to the operation of laws for the regulation of the liquor traffic, indicating our sympathy with the endeavor to lessen as much as possible the dreadful effects which it entails upon our own land, as well as upon all civilized lands. And we wish to do all in our power to secure the co-operation of the medical men of America in the labors of benevolent men of all callings to correct, as far as possible, the curse of intemperance. No class in the community knows better than physicians do the bitter effects of intemperance; and none can more appropriately discuss these effects, or suggest methods for preventing them.

MEDICAL EDUCATION IN THE UNITED STATES.

In the *Report of Proceedings of the Illinois State Board of Health*, at its annual meeting, January 12–13, 1888, there is a very interesting review of the condition of medical education in this country. The data gathered by the Illinois Board of Health indicate a continuing improvement in the methods and an elevation of the standard of medical education in the United States. The report states that there are now one hundred and fourteen medical schools which exact an educational preparation of intending matriculates, as against forty-five formerly; forty-three schools now require attendance upon three or more courses of lectures as against twenty-two formerly; and fifty-seven provide for a three or four years' graded course. The average length of each course of lectures has increased, and sixty-three schools have terms of six months or more. One of the effects of a higher standard of medical education is seen in a decreasing proportion of graduates to matriculates.

These facts may serve to encourage those who desire and labor for a high standard of medical education in America. An improvement in this respect is much needed. We are not of those who think that one standard can be made for all the schools of this country; because we think that the varying conditions of wealth and population make it impossible to require of those who practice in different portions of this wide land the same degree of education. There are many sections of the United States which would have no physician at all, if no one could be a physician except at a cost of time and money which but few can spare. For this reason we see a distinct field of usefulness for medical schools which exact attendance on only two courses of lectures. But we think that such schools should not pretend to exact more, and that they should use their "liberty as not abusing it;" and that they should make the very most they can of the time during which their students are under their control. The course of time and the material development of our country may be trusted, we believe, to bring about an improvement all along the line of medical education; but no effort should be spared to raise the standard everywhere, so that it should nowhere be despicable. It is not enough to show that excellent practitioners come—as they do—every year from schools with short terms of study; for there can be no doubt that these same excellent practitioners would do their work better if they studied a longer time. So it is a good thing to encourage and stimulate all the medical schools of America to set before them a high ideal, to which some can and will come nearer than

others, but toward which all should strive to approach as much as the conditions peculiar to each will permit.

LIPANINE—A SUBSTITUTE FOR COD-LIVER OIL.

In the *Therapeutische Monatshefte*, February, 1888, Dr. J. von Mering has an interesting paper, in which he discusses the relative merits of brown and white cod-liver oil, and expresses the opinion that the generally admitted superiority of the former is due to the fact that it contains a larger percentage of oleic acid than the latter does. This opinion has led him to make an artificial compound of olive oil and oleic acid—six parts of the former to one hundred of the latter—which is less objectionable than brown cod-liver oil, on the score of taste, and which seems to possess many of the nourishing properties of the latter. This compound is now introduced in Germany under the name of "Lipanine." According to von Mering, it is not disagreeable in taste or smell, and it is very easily digested. It is easily emulsified in a weak alkaline solution, corresponding to the alkalinity of the contents of the bowels, and hence it is easily absorbed by the lacteals of the intestines. As a result of this fact it is possible to administer it in large doses and for a long time without arousing disgust or causing indigestion. Von Mering has given lipanine to more than forty patients in six months, thirty of them being children. All took the compound well, and it never caused nausea, vomiting, indigestion, or diarrhœa. The children to whom it was given were scrofulous or rachitic; and of the adults, four had phthisis and ten had diabetes. In all these cases the patients gained in weight and their general condition improved. The dose administered was from one to four teaspoonfuls daily to children, and from two to six teaspoonfuls daily to adults.

The results of the administration of lipanine, announced by von Mering, suggest the advisability of testing this remedy in this country. It is so easy to make and so convenient to administer that enterprising pharmacists may be expected to place it soon before the medical profession of America. A palatable substitute for cod-liver oil is a thing much to be desired, and we hope this one may prove as valuable as its inventor believes it to be.

NERVE SUTURE AND NERVE STRETCHING.

A great deal has been done in the last few years—especially in Europe—in the direction of uniting the separated ends of divided nerves, and a number of methods have been devised by which the ends might be brought together when the gap between them was considerable. Various processes of grafting, by flaps and by the interposition of materials intended to serve as a sort of scaffolding for the budding prolongations of the cut ends have been devised, and have been employed with considerable success. But only recently Prof. Max Schüller, of Berlin, has put into practice a plan which promises better results than any which we have yet seen proposed. This plan consists in making use of the well-known elasticity of the nerves, by laying bare a portion of the central, and, if convenient, of the peripheral end, and then stretching them over the gap until they meet and may be directly united by sutures of catgut. In the *Wiener Med. Presse*, January 29, 1888, Schüller reports a most interesting case in which he employed this method, with signal success. The patient was a worker in a chemical establishment, who in November, 1884, wounded himself in the palm of the right hand with a piece of glass broken from a bottle which he was corking. The symptoms pointed to a division of the median nerve; and when Schüller operated in May, 1885, soon after first seeing the patient, this was found to have occurred, and also, that a piece of glass was embedded in the imperfect scar at the seat of the wound. The operation consisted in laying bare the nerve from the lower part of the forearm to the middle of the palm, excising the scar tissue, removing the fragment of glass, and uniting the severed parts and branches of the nerve with fine catgut sutures. After this the wound in the skin was closed and dressed antiseptically, and

the hand and arm were fixed upon a suitably curved dorsal splint.

The issue of this operation was most satisfactory, and furnishes strong evidence of the value of the method. In carrying it out it would be well to follow the example of Schüller in sparing the nerve-fibrils as much as possible when applying the sutures, and in passing these very carefully, with delicate curved needles, such as are used in stitching a wounded bowel, through the sheaths of the nerve only. So far as the extent to which a nerve may be safely stretched is concerned, Schüller believes, from the result of his experience, and of certain experiments which he has made, that a gap of an inch and a half in the main nerves of the extremities can be bridged in this way. Violent and too extensive stretching would not commend itself to any prudent surgeon; but, within the bounds suggested by Schüller, we think that nerve stretching will prove a very valuable preliminary to nerve suture.

PASTEUR AND PESTILENCE.

It is reported from London that the inhuman proposition made some time ago by Pasteur, to send to Australia the germs of fowl-cholera, to be scattered among the rabbits, which prove such a nuisance there, is being carried out. It is stated under date of Feb. 27, that three agents of Pasteur have sailed for New South Wales, with material to spread the fowl-cholera among the rabbits, in the hope of exterminating them. This incident, of heartless and cold-blooded cruelty, may perhaps open the eyes of some persons who have accepted the posing of Pasteur, and the claims of his admiring son-in-law that he is a great humanitarian. If those who live near him are to believed, there never was a man who more carefully calculated the commercial value of his scientific work, and this last act shows that he is a man, who for the hope of the large reward which has been offered for the extermination of rabbits in Australia, will deliberately sow among them the seeds of a slow and torturing disease. What is to be thought of the Government of Australia if it permits this plan to be carried out, we do not venture to say, since the plan has not reached the stage of execution yet. But we hope the people of Australia will find a way to prevent the carrying out of this mercenary and cruel scheme. Humanity should prompt them to this, not to mention the possibilities of danger to man himself which are involved in spreading a deadly disease among animals.

FORCIBLE FEEDING OF THE INSANE.

In the *Wiener Med. Presse*, February 5, 1888, Dr. Julius Rader, physician to the Austrian Insane Asylum at Ybbs, describes the case of a woman affected with delusional insanity, who indulged in periodical fastings from 1881 to 1887. The longest fast was for twenty-one days. The study of this case leads Rader to deprecate the practice of forcing food upon insane persons who have made up their minds to eat nothing. This practice he holds—and we believe with reason—to be not only useless but dangerous. That it is useless is shown by the fact that persons, both sane and insane, have been known to go without food for long periods of time without material disadvantage, and that the insane seem to bear fasting better than the sane. That it is dangerous is evidenced by the fact that not a few cases are known in which serious injury has been done to insane persons by the violence necessary to force food into their stomachs, which they can, and do sometimes get rid of immediately by vomiting. In addition to this, in a number of cases one effect of this vomiting has been to lead to aspiration of vomited matter into the lungs, and a consequent pneumonia.

Bearing these facts in mind, we can approve Rader's suggestion that more is to be feared than is to be hoped for from forced feeding of the insane, and that it would be well for those who have the care of these unfortunates to dismiss their alarm at an obstinate refusal to take food for many days, and to relinquish the notion that, under such circumstances it is desirable to bind the patient, introduce a stomach tube, and force food into an unwilling and intolerant guest.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

CONTRIBUTIONS TO THE STUDY OF THE HEART AND LUNGS. By James R. Leaming, M.D., Emeritus Professor of Diseases of the Chest and Physical Diagnosis in the New York Polyclinic, etc. 8vo, pp. 300. New York: E. B. Treat, 1887. Price, $2.75.

This handsomely printed book contains a series of papers on diseases of the heart and lungs, read and published by the author between 1865 and 1875, and discussions of the therapeutic value of chloride of ammonium, mercury and thuja occidentalis. Most of these papers have been before the profession long enough to receive criticism from those who dissented from any of the views expressed, and the author has presented them again in the shape which his mature reflection approves, after giving careful consideration to the opinions which have been expressed in regard to them.

The result is a book which contains much valuable information in regard to various physiological conditions of the heart and lungs, and which is calculated to be useful, as it certainly is interesting.

THE INTESTINAL DISEASES OF CHILDHOOD. By A. Jacobi, M.D., President of the New York Academy of Medicine, etc. 5½ x 7 inches, pp. xvi, 301. Detroit: Geo. S. Davis, 1887. Price, 25 cents.

This book is the number for September, 1887, of what the publisher calls "The Physicians' Leisure Library." The numbers are supposed to be issued monthly, at a subscription price of $2.50 a year. Some of these books are excellent; but some of them bear manifest marks of being made to order. This one is an example of what we mean. It is divided into chapters or sections, some of which are ridiculously small: one containing exactly four lines. Of course what Dr. Jacobi says about the diseases of children deserves respectful attention; but we regret that he has in this instance consented to make a book which few lovers of books will think worthy of his reputation. The publisher's part of the work is marked by evidences of carelessness and a lack of a good book-instinct, which are abundantly illustrated in the table of contents.

TRANSACTIONS OF THE NEW YORK STATE MEDICAL ASSOCIATION FOR THE YEAR 1886. Vol. iii. Edited for the Association by Alfred Ludlow Carroll, M.D. 8vo, pp. viii, 601. Concord, N. H.: Republican Press Association, 1887.

This is an exceedingly handsome volume, which does equal credit to the scientific status of the State Medical Association of New York, and the wisdom and skill of the Committee on Publications and of its Editor. The papers cover a wide range of medical and surgical subjects, and the book contains memoirs and handsome portraits of Drs. Austin Flint, Frank H. Hamilton and John P. Gray. Where there is so much of value and interest it would be impossible to select a few papers for notice without being invidious; and we must content ourselves with expressing our admiration of the whole in this general and unstinted way.

THE BONES OF THE LEG CONSIDERED AS ONE APPARATUS. By Thomas Dwight, M.D., Parkman Professor of Anatomy at Harvard University. 8vo, pp. 18. Boston: Cupples & Hurd, 1888. Paper. Price, 25 cents.

This interesting monograph upon the tibia and fibula, studied in their relations to each other and to the neighboring soft and hard parts, is the substance of a lecture delivered at the Harvard Medical School, Nov. 14, 1887. It contains a description of the shape and direction of various parts of these bones, and explains the mechanical principles involved in their reciprocal relations, and is illustrated with diagrams showing the bones in profile and in cross-section.

THE NATIONAL SIN OF LITERARY PIRACY. By Henry Van Dyke, D.D. Small 8vo, pp. 23. Paper. New York: Charles Scribner Sons, 1888. Price, 5 cents.

This little tract on what is now a burning question contains a sermon recently preached by Dr. Van Dyke at his church in New York. It is reprinted, and sold at a nominal price by the Scribners as a contribution to the discussion of international copyright, which is now going on in literary and commercial centres. Dr. Van Dyke takes a firm stand against the pillaging of authors which is so common on both sides of the Atlantic; but turns his attention especially to that which prevails in our own country. It is true that the English need such censure as he administers to our own countrymen as much as the latter do; but we agree with his obvious opinion that we should pluck the beam out of our own eye before undertaking any operation upon the eye of our brother. We share the growing desire in this country for an international copyright law, and welcome this effort to hasten its coming.

THE NEW YORK MEDICAL JOURNAL VISITING-LIST AND COMPLETE ACCOUNT BOOK. Prepared by Charles H. Shears, A.M., M.D. New York: D. Appleton & Co. Price, $1.25.

Our high regard for the *New York Medical Journal* makes it unpleasant for us to say what we think about this new candidate for professional favor. The publishers' opinion is that it is "without doubt the most perfect visiting-list ever offered to the profession, as it possesses all the advantages without the objectionable features found in all others." Our opinion is that it lacks the most important advantages of most visiting-lists, and, in fact, is not a visiting-list at all. It may meet with approval by physicians; but we think it will not. As a book, it is very dear indeed, at the price asked for it.

Pamphlet Notices.

Conservative Gynecology. By George F. Hulbert, M.D., St.. Louis. From the *Weekly Medical Review*, Dec. 17, 1887. 10 pp.

Recent Advances in the Surgery of the Brain and its Coverings. By Charles B. Nancrede, M.D., Philadelphia. From the *Medical News*, Jan. 28, 1888. 28 pp..

Report on the Progress of Forensic Medicine and Toxicology. By Martin V. B. Clark, M. D., Sutton, Nebraska. *State Journal Company*, Printers: Lincoln, Nebraska, 1887. 16 pp.

Lyssa and the Pasteur Fiasco. By N. E. Brill, A.M., M.D., New York. From the *Journal of Comparative Medicine and Surgery*, January, 1888. 23 pp.

The Significance and Localization of Pain in Pelvic Diseases. By Henry Coe, M.D., New York. From *Gaillard's Medical Journal*, February, 1888. 10 pp.

Contribution à L'etude de la Syphilis des Fosses Nasales. Par le Dr. E. J. Moure, Paris: *Octave Doin, Editeur*, 1888. 12 pp.

Sub-pubic Dislocation of the Left Femur. By J. S. Wight, M.D., Brooklyn, N. Y. From the *Transactions of the Medical Society of the State of New York*, 1887. 4 pp.

—Dr. Hulbert's paper contains an argument against the procedure of divulsion of the cervix uteri, which he believes to be a pernicious practice. His argument includes a careful study of the anatomy and physiology of the uterus and of the mechanical principles involved in flexions and so-called stenosis. The latter he believes to be misunderstood by many gynecologists, and he criticises sharply the common illustration, by a bent tube, of the condition supposed to obtain in cases of flexion of the uterus.

—Dr. Nancrede's paper contains a very good summary of the present state of knowledge in regard to the proper way to treat injuries of the brain and its envelopes. The author, like most surgeons of the present day, favors active surgical interference in cases of actual or probable fracture of the skull, of wounds passing into or through the bones of cranium, of tumors, abscesses, morbid growths, and hemorrhages within it. He also favors operations for epilepsy when this seems to be caused by a removable mechanical irritant. We do not think that the surgical world will be as much surprised at his statements as he seems to fear they will be; for most of them are to be found elsewhere, and surgeons who read have had a fair a chance to get used to them.

—Dr. Clark's pamphlet contains a full account of his investigations in two cases of supposed felonious poisoning. In one, the poison used was arsenic, and in the other it was strychnia. In both cases the patients died, and a trial for murder followed. Both of the accused persons were acquitted on the ground that it was not proved that they had administered the poison. The details of Dr. Clark's analysis are interesting and instructive, and indicate the thoroughness with which he did his work, leaving no possible doubt of the presence and nature of the poison in each case. In the second case, he came near losing his life from testing an extract of the stomach—supposed to be strychnine—upon himself.

—Dr. Brill applies to the popular theories in regard to hydrophobia, and to the claims of Pasteur in regard to his preventive inoculations, an uncommonly keen analysis and criticism. It is still held by men of deserved eminence in the medical profession that hydrophobia is a specific, inoculable disease; and some of them still trust in the assertions of Pasteur in regard to his method of treating it. But the number of those who have studied both so-called hydrophobia and Pasteur's shifting announcements is increasing, and hydrophobia and Pasteurization are less the rage than they once were. It is to be hoped that hydrophobia will yet disappear—as witchcraft has disappeared—and that such works as this of Dr. Brill, which we strongly recommend to the attention of our readers, will be estimated, as it deserves to be.

—Dr. Coe's interesting paper on pelvic pain treats of the nature and character of this important means of diagnosis, and advocates the use of electricity to remove it. The author believes that pelvic pain originates more frequently in the perimetric tissues than in any particular organ, and that it may radiate from inflammatory foci in the peritoneum or connective tissue surrounding the pelvic organs. For this reason operations upon these organs may fail to cure the pain, which may be materially relieved by the use of electricity.

—Dr. Moure's pamphlet contains a detailed account of two cases of syphilitic lesions within the ala of the nose. In one of them the lesion was the initial lesion of syphilis—a chancre; in the other it was a syphilitic gumma. Both lesions are extremely rare in this situation, and great interest attaches to an authentic account of such well studied and well described cases.

—Dr. Wight describes the case of a man upon whom four barrels of flour fell, producing a sub-pubic luxation of the head of the left femur and a compound fracture of the right femur. The main interest in the history of this case is connected with the manner in which the luxation was reduced—being converted first into a thyroid luxation, which was then corrected by replacing the head of the bone in the cotyloid cavity. This method is not new; but Dr. Wight's way of carrying it out was more or less extemporaneous and worthy of imitation. It consisted in passing the patient's leg over the surgeon's right shoulder, and combining traction, adduction, elevation, and manipulation with the hands until the head of the bone slipped into the thyroid foramen, after which flexion of the thigh, abduction, traction, and rotation inward, brought it into its normal position.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*The Annals of Surgery*, which has just entered upon its fourth year, under the management of Dr. L. S. Pilcher, of Brooklyn, and Dr. C. B. Keetley, of London, is the only periodical, published in the English language, which is devoted exclusively to surgery. Each number contains original articles, and admirable summaries of surgical progress, as well as able editorials on subjects of timely interest. *The Annals* are published monthly at St. Louis, in octavo form, about 80 pages, by J. H. Chambers, price $5.00 a year. We can heartily commend it to the attention of those of our readers who have an interest in surgery.

—Blizzards, apparently, are becoming ordinary occurrences in Dakota, for a Western exchange remarks casually that, "after a blizzard the other day," Dr. Wheeler, of Grand Forks, and a number of friends took a ride on the doctor's ice-boat, going at the rate of 23 miles an hour.

Correspondence.

Prescribing Druggists.

Editor Med. and Surg. Reporter:

I was called to-day to visit a patient seriously ill with pneumonia following measles, and learned that she had been taking for several days a "cough mixture" prescribed by an M.D. druggist for a *bad cold*, so that important time for treatment of her disease had been lost. Returning to my office I found in the Reporter, February 11, an editorial upon the subject of "prescribing by druggists," which prompts me to write a few lines —not because I believe it will mitigate the evil here, but in the hope that it may arouse others in the profession to demand our rights, and to teach druggists to confine themselves to their legitimate business. This can only be done by concert of action on the part of the profession; for so long as a few physicians pander to the mania of druggists for prescribing in order to secure their influence for patronage, so long will druggists continue the practice. They cannot do it for pecuniary gain, because usually a prescription would prove more remunerative than the medicine furnished. Druggists expect physicians to send their prescriptions to them, they do all in their power to deprive the physician of his fee. This is the pecuniary standpoint, but there is another of more importance, a druggist may have a diploma to practice medicine, but when he undertakes to diagnosticate and treat diseases from behind his counter, without examining the patients carefully, and sometimes without ever seeing them, he is assuming a very great responsibility, it is not only the harm his medicine may do, but there is important time lost; and if a physician is called and the patient dies, the credit of the result does not go to the druggist but to the doctor. If the public could only know the evil this prescribing over the counter entails upon the patient, no druggist—whether he be an M.D., Ph.D., or no D. at all—would dare do it. A druggist may say that if he do not prescribe, the patient and his patronage will go to another druggist. But if there were concert of action among physicians, druggists would soon learn that the patronage of the physician is worth the most. This is a growing evil, and as the profession is becoming more and more crowded, M.D.'s are entering more into the drug business, and competition for prescribing is proportionately increased. Our State and county societies should take some decided steps in the matter, and our legislatures should be petitioned for some law to protect the people. I venture the assertion that druggists to-day do ten-fold more harm in prescribing over their counters and selling quack and proprietary medicines than all the charlatan doctors combined.

Yours truly, B. P. Reese.

Staunton, Va.,
February 3, 1888.

Amylene Hydrate.

Editor Med. and Surg. Reporter:

Sir:—Where can I obtain amylene hydrate, and at what price?

Yours truly,
A. S. Maxson, M.D.

Milton Junction, Wis.

[Amylene hydrate is tertiary amylic alcohol. It is a clear fluid, of a camphoraceous taste and odor, soluble in eight parts of water, and in alcohol in all proportions. A convenient method of administration is with licorice:

Amylene hydrate,
Fluid ext. licorice.....āā..f℥j
Water, to make.....f℥j
Mix.

This may be given in a single dose; but Avellis, in the article referred to in the Reporter, February 14, 1888, p. 154, has obtained good results from doses of one half to two-thirds of this quantity. The drug may be obtained from any reliable chemist, at about 60 cents an ounce.—Ed. Reporter.]

Sudden Death in Typhoid Fever.

With reference to his letter in the Reporter, February 25, 1888, p. 220, Dr. Hunter writes that "the 24th day" referred to the day of the month, not the day of the disease, as the patient lived only fifteen days. His temperature on the fourteenth day of his disease (January 24) was 100½° F., not 101½°.

—*Public Opinion*, Feb. 11, 1888, states that a new gas has been discovered in Germany by Dr. Theodore Curtius, who has succeeded in preparing the long-sought hydride of nitrogen, amidogen, diamide, or hydrazine, as it is variously called. This remarkable body, which has hitherto baffled all attempts at isolation, is now shown to be a gas perfectly stable up to a very high temperature, of a peculiar odor—differing from that of ammonia—exceedingly soluble in water, and of basic properties. In composition it is nearly identical with ammonia, both being compounds of nitrogen and hydrogen.

Notes and Comments.

A National Pharmacopœia.

The following bill, relating to the publishing of a National Pharmacopœia, has been introduced into the House of Representatives by Mr. Samuel J. Randall.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of the Treasury shall, as soon as practicable, detail two officers of the Marine Hospital Service, and the Secretary of War shall detail two officers of the medical staff of the Army, and the Secretary of the Navy shall detail two officers of the medical staff of the Navy, for the duty of compiling and preparing a pharmacopœia, which shall be known as the National Pharmacopœia of the United States of America, and shall be held and accepted as the standard for the purveying, compounding, and dispensing of drugs or medicinal agents, and shall be taken as authority in the Treasury Department on all questions arising under the tariff laws of the United States with regard to the nomenclature, description, and purity of drugs or remedial agents, and shall further be received as evidence in the United States courts. And the matter contained in the said pharmacopœia shall be free for use by all authors and commentators for the benefit of the medical and pharmaceutical professions and of the community at large; and it shall not be lawful for any one to reprint and publish the said pharmacopœia as a whole.

Sec. 2. That the medical officers detailed as above provided shall invite the American Medical Association and the American Pharmaceutical Association at the next annual meeting, to form committees of not more than three members from each of the said associations, which committees, if so appointed, may co-operate with the above-named medical officers in the preparation of the said pharmacopœia, forming a board, which shall have power from time to time to add to its number as may in its judgment be necessary, and which shall elect a chairman and a secretary, and adopt such rules as it shall see fit for the expediting and perfecting of the said pharmacopœia, which, when completed, shall be printed under the supervision of the said board; and an edition of not less than five thousand copies shall be printed for use in the several departments of the government of the United States; and copies may be furnished to private persons in accordance with the provisions of section thirty-eight hundred and nine of the Revised Statutes.

Sec. 3. That for the purpose of defraying the necessary expenses of preparing the said pharmacopœia the sum of five thousand dollars is hereby appropriated out of any moneys in the Treasury not otherwise appropriated, and the same shall be disbursed under the regulations to be prescribed by the Secretary of the Treasury.

Sec. 4. That the said pharmacopœia shall be revised once in ten years, upon the plan embodied in this act.

Legal Relations of Attending Physicians to their Hospitals.

One of the staff of the Queen's Jubilee Hospital, London, was dismissed by the managing committee of the Hospital because he accepted an appointment in another hospital in which homœopathic methods are recognized as an optional mode of treatment. The dismissed physician, whose name is Millican, appealed from this action to the court. Mr. Justice Manisty, before whom the action was tried, animadverted strongly in his judgment on the course which the committee of the hospital had adopted. For this course he has since been rebuked by the Court of Appeals. The doctrine of the latter court was thus stated by the presiding judge: "As medical officer, he would have a license to use certain rooms and certain furniture in the hospital. He would have *only a license, and not an interest in the property.* It followed from that, whether the relation between the plaintiff and the defendants was a contractural relationship or not, the relation was a strictly personal relation. Even, therefore, assuming that the defendants committed a wrongful act in putting an end to that personal relationship, the authorities were clear that the plaintiff was not entitled to an injunction. The plaintiff must bring his case within the principles upon which Courts of Equity will give such relief. Assuming, then, that there was a contract here, Courts of Equity never dreamt of enforcing by injunction agreements that were strictly personal in their nature." Lord Justice Fry remarked: "The position of the plaintiff was twofold. He was a subscriber to the hospital, and so a governor; and that position was not interfered with. He was also a medical officer. It was not necessary to consider whether the appointment constituted a contract with him or not. But, if it did, it created a purely personal relationship."—*Lancet*, Jan. 21, 1888.

Can Asses Vomit?

An interesting physiological point, says the *Lancet*, Dec. 31, 1887, is now being discussed in Paris. M. Zola, in his last work, "La Terre," depicts an intoxicated ass, and concludes with an account of the animal in the throes of sickness. M. Sarcey has taken offence at this unpleasant piece of realism, and, in a review of the work, affirmed that the ass was incapable of being sick, and brought forward the evidence of a veterinary surgeon to the effect that the structure of the stomach of an ass renders vomiting impossible. M. Zola writes back, and turns the tables on his adversary by stating that he had read up the principles of equine or asinine physiology before venturing to describe the matter in question, and refers the veterinary surgeon to his studies. In point of fact, M. Zola is perfectly correct. It is commonly, but incorrectly asserted, that the horse and ass cannot vomit. It is true that they vomit rarely and with great difficulty; the reasons being that the stomach is small, that the œsophagus opens into the stomach much nearer the pylorus than in the dog or man; so that the cardiac portion forms a large sac, against which the contents of the stomach are pressed when efforts to vomit are made. The contents of the stomach are, moreover, usually rather dry, and do not remain long in the interior of that viscus; and, finally, the œsophageal aperture is small and highly muscular. The latter point is undoubtedly of importance, since horses, and we presume asses also, vomit readily enough when, by disease or operation, the cardiac sphincter is paralyzed. M. Zola, if not very delicate, at least studies his art.

Good Advice.

Rev. Dr. Dallinger, speaking with the double authority of a minister of religion and a man of science, has been saying a few words of good, sound sense to Yorkshire people about the mockery of prayer to God for the abatement of small-pox, without the diligent use of all human means to this end. There cannot be a case of small-pox in a community without blame attaching either to the patient or to those responsible either as parents or as guardians of the public health. It is averred that men and women, half recovered from the disease, have been going about in Sheffield in public vehicles, or to places of amusements. This is an outrageous breech equally of sanitary law and of scriptural law of consideration for others. Small-pox is a disease from which everyone may be absolutely protected by vaccination and re-vaccination, so that to have it is almost a crime.—*Lancet*, February 11, 1888.

Artificial Cow's Milk.

Le Concours Médical, January 14, 1888, says that Dr. Ledentu has communicated to the Society of Medicine of Trieste the following mixture, which seems to him to reproduce with sufficient exactness the composition of cow's milk. He has himself employed it with great success forty-four times in fifty-one cases of cholera infantum. The following is the mixture:

White of egg	ʒiv
Oil of sweet almonds	ʒviiiss
Sugar of milk	ʒx
Carbonate of soda	gr.vi
Chloride of sodium	gr.iii
Neutral phosphate of lime	gr.viiss
Water	Oii

Make into an emulsion.

Acute Bright's Disease in Children.

In a paper on this subject read before the New York State Medical Society, on Feb. 8, 1888, Dr. A. Jacobi said that many cases run an insidious course, the temperature being low, and appearing lower than it is, for the incipient œdema lowers the surface temperature, and even the temperature taken in the axilla by the thermometer is deceptive. Œdema and dyspnœa are the first marked symptoms—œdema of the pericardium, lungs, glottis and brain. Increase of blood-pressure causes cerebral symptoms and cardiac trouble. Diarrhœa is also found. Sometimes the symptoms appear very suddenly—such as a sudden loss of sight. The urine contains albumin; although this is occasionally absent, and then the urine is scanty, of low specific gravity, containing very little urea. Casts and epithelia are found.

One of the causes of acute nephritis in the adult is wanting in children, for the arteries are not degenerated. The most frequent cause is the poison circulating in the blood in the acute infectious diseases, especially scarlatina and diphtheria, but it is very rare in typhoid fever, probably because the course of the latter is not so acute and the range of temperature during it is lower. Rheumatism is for the same reason also less frequently a cause, even when endocarditis is present. The author had seen it follow purpura, renal hemorrhage being one of the symptoms. It also complicates croupous pneumonia, and even catarrhal pneumonia and bronchitis. Irritant drugs cause it, and especially chlorate of potash.

Exposure to cold is a very frequent cause, and in these cases common symptoms are hæmaturia, or hæmoglobinuria, which may return with every fresh exposure. As to the prognosis of nephritis in typhoid fever it is sometimes bad, even fatal, but generally the patient recovers entirely. In scarlatina, chronic nephritis may result, or uræmia may set in early and cause death. In diphtheria, on account of the difference in the poison, the lower range of temperature, and the weak heart, hæmaturia is not so common. In some cases of diphtheria copious albuminuria may even be followed by improvement in the general condition.—*Medical Record*, February 11, 1888.

Formulæ for Eczema.

The following formulæ are from the *Zeitschrift für Therapie:*

℞ Olei cadini (*vel* rusci),
Olei olivæ.....āā ʒi
Lanolin. pur.....ʒiss

Or,

℞ Olei ruscı,
Zinci oxidi,
Olei olivæ.....āā ʒi
Lanolini pur.....ʒiss

M. Sig.—For dry scaling eczema.

Lanolin is also especially advantageous in the form of inunction in all cases in which there is a dry scaling skin, and can be either used by itself, mixed with oil to bring it to the proper consistence, or in the form of the following ointment:

℞ Acidi boracici.....ʒj
Olei olivæ.....ʒi–ij
Lanolin. pur.....ʒiss

This borated lanolin ointment accomplishes excellent results in the different affections of the lips in children, which so frequently present themselves for medical treatment.

How to Preserve Ligatures.

Prof. S. W. Gross condemns the use of carbolized oil for preserving *catgut ligatures*, as it forms a nidus for germs. Ten per cent. carbolized water does the same thing unless changed every two weeks. He recommends the following way to preserve them: Take the animal ligature, prepare a 1 to 5 aqueous solution of chromic acid:

Acid. chromic.....ʒj
Aquæ.....fʒv

M.

Add one ounce of the above solution to five ounces of glycerine, place the ligatures n this solution, and leave them there for one week; then take them out of this solution and hang them up until they are perfectly dry. Placed in the following solution they will keep until needed:

Alcohol.....parts 15
Glycerin.....parts 1
Acid. carbolic.....10 %

M.

If thrown into a 1–1000 solution of corrosive sublimate a few minutes before using, they will become soft and pliable.—*College and Clinical Record*, February, 1888.

Emulsions with Saccharin.

This new drug seems to be obtaining a stronger foothold in England than in this country. A. W. Gerard, professor of pharmacy in the University College, uses it in emulsions, and prepares the following formulæ:

EMULSION OF COD-LIVER OIL.

To make an elegant preparation, with the odor and taste well masked:

Take of
Cod-liver oil.....4 fl. ozs.
Powdered gum acacia.....1 oz.
Oil of cassia.....4 min.
Oil of almond.....4 min.
Saccharin.....2 grs.
Water to make.....8 fl. ozs.

Mix the oils with the gum and saccharin in a dry mortar, add 2 fluid ounces of water in one volume, stirring till the emulsion is formed; finally, add sufficient water to make 8 fluid ounces.

EMULSION OF CASTOR OIL.

To make an emulsion in which the oil is well disguised:

Take of
Castor oil.....1 fl. oz.
Powdered gum acacia.....3 drs.
Essential oil of almond.....2 min.
Oil of cloves.....1 min.
Saccharin.....1 gr.
Water to make.....4 fl. ozs.

Mix the oils with the gum and saccharin in a dry mortar, add 4 drams of water at once, stirring till the emulsion is formed; dilute to 4 ounces with water.

YOLK OF EGG EMULSION OF COD-LIVER OIL.

Take of
Cod-liver oil.....4 ozs.
Yolk of egg.....2 ozs.
Common salt.....25 grs.
Saccharin.....2 grs.
Oil of cloves.....8 min.
Water to make.....8 fl. ozs.

Rub the oils gradually with the yolk of egg, salt, and saccharin till an emulsion is formed, make up 8 ounces with water and shake well.—*National Druggist*, January, 1887.

Anomalous Features in a Case of Ovariotomy.

At a meeting of the San Francisco County Medical Society, December 27, 1887, Dr. O. O. Burgess reported a case of ovariotomy in a young woman, in which the operation had been rendered very difficult from the peculiar anatomical arrangement of the parts. The two ovaries had coalesced and degenerated so as to form one tumor, from each side of which a tube, which at first sight resembled intestine, but was afterwards found to be Fallopian tube, passed to the uterus, while from the vertex of the tumor a fibrous band passed upwards and gradually disappeared in the peritoneum. The fact that the displacement of the uterus was congenital, its descent having been prevented by the fibrous band, made it very strange that there never had been any disturbance of the menstrual function.

Another interesting part of the history of this case, is the fact that menstruation has been regular since the operation.—*Pacific Med. and Surg. Journal*, February, 1888.

Warning Apparitions.

In an article entitled: "Have ghosts been seen?" in the *Cosmopolitan*, January, 1888, Mr. Richard A. Proctor discusses the scientific status of the stories of apparitions seen at about the time of the death of friends or relatives, and the explanation offered in regard to them.

The coincidence explanation, he says, which disposes fully of even the best-authenticated ghost and goblin stories, fails entirely in the presence of the phenomena we are considering. Professor DeMorgan, a master of logic, long since pointed out its absurdity as thus applied. Among the multitudinous sights and sounds that, under favoring conditions, may be mistaken for apparitions and their utterances, a considerable number is bound to be strongly deceptive (the human mind being what it is), and there cannot but be some that seem to escape all explanation. But the special characteristic of the influences and appearances we are considering here is that they are so unusual as to convince the persons affected that something of a dreadful or most impressive nature has affected a dear friend or relative, and they are almost always, if not invariably, confirmed by the event.

As to the question of fact involved in these stories, he says: "It appears to me that the evidence regarding the communication of impressions from mind to mind over great distances, in such sort that apparitions of distant persons dying or suffering seem to be seen by their friends or relatives, is too strong to be rejected by any conscientious student of facts." He believes that science is no more justified in rejecting this evidence merely because no explanation is available than astronomers would be justified in rejecting the observed fact that bodies influence other bodies from a distance, merely because, as Newton himself admitted, no one can explain how matter can act where it is not. Some communication, he says, there must be between sun and planet, between planet and satellite, and beyond each solar system between sun and sun and between galaxy and galaxy; but no one has yet shown what that communication may be. In like manner, even the most cautious student of science may well believe that there may be some means of communication, under special conditions, between mind and mind at a distance, though no one may be able to explain how such communication is brought about.

For Chapped Hands.

The *American Druggist* recommends the following formula:

White wax	℥xiv
Spermaceti	℥iij
Cocoa butter	℥ix
Castor oil	℥ix
Oil of benne	℥vi
Melt and mix; then add glycerin	℥ij
Perfume as desired.	

This makes quite a nice preparation. Petrolatum is used instead of the oil of benne (sesame oil) by some, and is considered an improvement. Either, however, will do.

Pruritus Vulvæ.

An application which has proved of the greatest possible service in this obstinate and distressing affection is composed of

Cocaini hydrochlor	gr. xv
Aquæ destillat	q.s. ut ft. sol.
Lanolini	℥ss

This is to be applied to the itching parts.

For chronic Pelvic Peritonitis.

Dr. Cheron recommends:

Ammonii chloridi	℥iss
Syrupi aurantii cort	f℥vi

M. Sig.—One to five tablespoonfuls daily in water.

Putrid Diarrhœa.

Bouchard's formula is:

Naphthalini,	
Sacchari	āā ℥iss
Essentiæ bergamot	gtt. j–ij

Div. in chart. No. xxv. Dose, one powder every hour.

Photographing anatomical Preparations.

A novel and interesting application of photography was made in Philadelphia recently, and consisted of the photographing of anatomical subjects at night, immediately after their dissection. This was the experiment tried at Dr. George McClellan's "Pennsylvania School of Anatomy," on Tenth street, above Walnut. Dr. McClellan complained that the drawings which he had been able to obtain, while the finest of their kind, were idealized too much and did not present the subject as the student finds it. He also said that the tissues change so rapidly when exposed to air that photographs, unless taken immediately after dissection, gave no adequate idea of the objects, and the light in the clinic hall was of such a character that photography by the ordinary methods was out of the question. Mr. Buchanan undertook to overcome the difficulties by doing the work at night, and with the artificial light compound. The camera was focussed by aid of the light from a match, and very rapid plates were used. About 50 grains of the compound were placed on the edge of a small iron shovel and held a little behind but on the level of the lens; and, after the plate-holder slide had been withdrawn and the lens uncapped, a light was applied to the compound. There was a blaze of intensely white light, lasting for about one-tenth of a second, and the exposure was complete. Six plates were used, and in the cases of three or four a screen of tracing muslin was hung between the flash and subject. The plates were developed the next day and proved to be excellent printing negatives, the details being brought out so sharply that the prints are pronounced to be of very considerable scientific value.—*Ledger*, December 30, 1887.

Gargle for Chronic Pharyngitis.

Endler recommends the following solution as a gargle in chronic pharyngitis:

Zinci sulphatis.....gr. xv
Aquæ menth. pip.....f℥vj
M. Sig.—Use as a gargle four times a day.

He says that his own pharyngitis which had existed for three months, was cured after using this solution continuously for eight days; and that his patients obtained the same successful results. In especially sensitive persons a weaker solution may be employed. —*Berliner klin. Wochenschrift.*

—Diarrhœa and cholera morbus are said to be epidemic in Minneapolis, Minn.

NEWS.

—Emile Rousseau, the eminent French chemist, died on February 6. He was 72 years old.

—Small-pox which has been epidemic in San Francisco, has now become scattered throughout the State.

—A new medical journal is announced to appear in Berlin under the title of the *Berliner Clinik*. Prof. Fürbringer and Dr. Hahn are the editors.

—Professor Brunetti, of the University of Padua, Italy, was recently suspended by ministerial decree, on the charge of inciting the students against his own colleagues.

—The Italian troops at the seat of war in Abyssinia are suffering from fever and intestinal affections, due, it is said, to the continued rainfall, succeeded by sudden elevations of temperature. Of the 18,000 men composing the expeditionary force, about 1,000 are in hospital. The death rate, however, is still very low.—*Lancet*, Feb. 11, 1888.

—The *British Med. Journal*, January 28, 1888, states that Mr. Thomas Godart, late Librarian of St. Bartholomew's Hospital, London, died November 5, 1887, at Sydney, New South Wales, whither he had gone on account of ill-health. He assisted Mr. Luther Holden by engraving the lithographs for Holden's *Osteology*. The best specimens of Mr. Godart's skill are his colored pathological drawings.

—The *American Lancet*, February, 1888, says: Of the one thousand physicians in Louisiana, only one hundred and seventy-six are members of the State Medical Society. Only about half the counties have representatives in the State Society. Why is this, when across the river in Texas the profession is organized with wonderful completeness? There is a chance for some missionary work in the profession of Louisiana.

—Rev. Dr. Leonard Bacon is vigorously assailing, and Rev. Dr. O. H. Platt is as valliantly defending, the faith cure, at Waterbury, Conn. Both are doctors of medicine as well as of divinity, but thus far the faithists have been unable to cure Dr. Bacon of his skepticism. In Jersey City, N. J., a butcher, John Elsey, was cured, or thought he was, of a bronchitis by this simple method, and he has erected a chapel in that city as a mark of his gratitude.

—A physician was recently charged before a Berlin court of justice with assault under peculiar circumstances. It seems that a boy four years old was brought before him

for treatment. Some local examination being necessary, the child began to scream and kick so violently that nothing could be done with him. After efforts to soothe him were entirely fruitless, the doctor lost patience and spanked him. The court held that the doctor had slapped the child with the object of doing him good, and dismissed the case.

—The Commissioners of Charities and Corrections of New York recently discussed a suggestion that the bodies of the unclaimed dead should be cremated, instead of buried, as is now done. The commissioners wrote to Corporation Counsel Beekman asking his legal advice as to whether they had authority to make such disposition of those bodies. He has answered that they have not. The Commissioners are required to bury all such bodies in the usual manner, except when they are authorized to give the bodies to medical colleges.

—The *British Med. Journal*, January 28, 1888, reports that on Friday, January, 13, Dr. Eustace, a young practitioner at Alresford, Hants, was summoned at midnight, and found a patient suffering from uterine hemorrhage. This he stopped, but in the morning the patient was almost pulseless and sinking fast. Dr. Eustace, with no one to help him but an old woman, opened a vein in his arm and tried direct transfusion, but lost a quantity of blood. He then allowed over six ounces of blood to drop into a basin, injected it with a syringe, with the result that the patient recovered.

—The Seventh German Congress for Internal Medicine will be held at Wiesbaden from April 9 to April 12, 1888. Herr Leube of Würzburg will preside. The following subjects are to be discussed:

Monday, April 9.—Chronic diseases of the Heart muscle and their Treatment; Oertel of Münich, and Lichtheim of Bern. Tuesday, April 10.—Alcohol as a therapeutic Agent; Binz of Bonn, and Von Jaksch of Graz. Wednesday, April 11.—The Prevention and Treatment of Asiatic Cholera; Cantani of Naples, and August Pfeiffer of Wiesbaden.

The following addresses are already announced: Rumpf (Bonn), Floating Heart; Unverricht (Jena), Experimental Investigations concerning the Mechanism of Respiration; Adamkiewicz (Cracow), Combined Degeneration of the Spinal Cord; Jaworski (Cracow), Experimental Contributions to the Dietetics of Digestive Disturbances; Stiller (Budapest), Therapeutics of Basedow's disease, and the Diagnosis of Tumors of the Kidney.

HUMOR.

FLIMSEY—"I don't know how it is, but the smallest specimens of men invariably get the best wives." Mrs. F. (archly)—"Oh, you flatterer!"—*Boston Transcript.*

A CORRESPONDENT of a New York paper asks: "Can you give a young lady a cure for malaria? She lives upon filled-in ground." "Filled in ground" must be an unsatisfactory diet. She ought to try pork and beans.—*Pittsburg Chronicle.*

A YOUNG PREACHER picked up Bishop Pierce's hat and put it on his own head, and it was exactly a fit. "Why, Bishop," said he, "your head and mine are exactly the same size." "Yes," replied the Bishop, "on the outside."

CHRISTIAN SCIENTIST.—"Have you ever tried the faith cure for your rheumatism?" Patient.—"Yes, I'm trying it now. I've got in my pocket the left hind foot of a graveyard rabbit that was killed in the dark of the moon, and I'm blamed if I don't think it's helping me.—*N. Y. Sun.*

THE CHRISTIAN SCIENTISTS would have us believe that what we call pain is merely imaginary; but hang the imagination that keeps a fellow awake all night when he has a felon on his thumb! And we don't suppose it would it do any more good to poultice the imagination than it would the thumb.—*Norristown Herald.*

SCIENTISTS say that shutting the eyes makes the hearing more acute. This explains why a man can't sneak into the house at midnight and crawl up-stairs as noiselessly as a feather without being heard by his wife, who is asleep. If women were to sleep with their eyes open, married men would have more fun at the lodge when there is a protracted session.—*Norristown Herald.*

"THE FACT IS, doctor, I can't sleep at nights; have a pain in my chest, and my stomach is all wrong." Doctor (feeling his pulse)—"What is your business, sir?" He—"I am a broker and a member of the New York Stock——" Doctor—"Never mind the balance. I understand your case thoroughly. Here take this (slips a dollar into his hand) and go and get something to eat."

THE SICK EDITOR.—Doctor (to professional nurse)—"Well, how is he this morning?" Nurse—"Weaker, doctor. Been very sick all night, and looks like he was comatose." Doctor—"Hows his temperature?" Nurse—"One hundred and two degrees." Doctor—"How's his circulation?" Editor (with

a fearful yell)—"Biggest in New York! Biggest in the universe! Want an affidavit?" —*Burdette.*

When "Aunt Betty" Brooks, of Pike county, Pa., celebrated her one hundredth birthday on the 2d inst., she caught a cold, which caused her death. This shows that the celebration of one's one hundredth birthday is attended with some danger. If "Aunt Betty" had died in her ninetieth year, she would have escaped that fatal cold, but we don't suppose she thought of that.—*Norristown Herald.*

A Compliment to American Skill and Ingenuity.—*Journal de Pharmacie d' Anvers* gives a full account of the Newark artificial egg manufactory of New Jersey. This triumph of American skill has been received with amazement on the Continent of Europe. The author states that the eggs are so nearly perfect in appearance and taste that it is only a matter of time when the domestic fowl will be banished from the barnyard. It is expected, in the near future, that the problems of life will be solved by these eggs, when properly heated, bringing forth well-feathered chicks.

OBITUARY.

MILTON B. MUSSER, M.D.

Dr. Milton B. Musser, a well-known physician of West Philadelphia, died March 2, 1888, in the 42d year of his age. He had had symptoms of heart failure for some months before his death. Dr. Musser came of a family of physicians—his grandfather, great-grandfather and uncle were physicians, and a brother and a number of cousins are now in active practice. He was graduated from Jefferson Medical College in 1868, and at the time of his death was attending Obstetrician to the Philadelphia Hospital, a member of the College of Physicians, of the County Medical Society and of the Obstetrical Society of Philadelphia. He leaves a wife and three children.

L. M. SERVICE, M.D.

L. M. Service, a well-known physician, of Philadelphia, died February 27, 1888, at the age of 68 years. He was born in Washington county, Pennsylvania, and in early life was a school teacher. He was graduated from the Jefferson Medical College in 1848, and from that period until within a short time of his death he had an extensive practice in Philadelphia, Montgomery and Delaware counties. He leaves a widow, three sons and one daughter.

D. ELLIS BYRD, M.D.

Dr. D. E. Byrd died January 25, 1888, at Marvell, Ark., after a brief illness. He was graduated from the Richmond Medical College in 1863, and after serving as surgeon during the late war began practice in Virginia. In 1870 he removed to Marvell.

OTIS F. MANSON, M.D.

Dr. O. F. Manson died in Richmond, Va., February 1, 1888, after a brief illness. He was 65 years old.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Feb. 19, 1888, to March 3, 1888:

Lieutenant-Colonel Edward P. Vollum, Surgeon, granted leave of absence for four months, with permission to go beyond sea, and to apply for an extension of two months. S. O. 41, A. G. O., Feb. 20, 1888.

Captain E. F. Gardner, Assistant Surgeon, granted leave of absence for one month and twenty-one days. S. O. 41, A. G. O., Feb. 20, 1888.

Appointment:

Paul Shillock, to be Assistant Surgeon, with the rank of First-Lieutenant, Jan. 31, 1888.

Changes in the Medical Corps of the Navy, for the week ending March 3, 1888:

Surgeon T. C. Heyl, orders to the Receiving Ship "St. Louis" revoked.

Surgeon C. H. White, present duty continued to Oct. 1, 1888.

Surgeon T. H. Streets, ordered to the Receiving Ship "St. Louis."

Surgeon M. C. Drennan, ordered to the Receiving Ship "Vermont."

Surgeon G. R. Brush, detached from the Receiving Ship "Vermont" and to the "Pensacola."

Passed Assistant Surgeon Victor C. B. Means, detached from Naval Hospital, New York, and to the "Pensacola."

Medical Inspector A. A. Hochling, detached from the "Pensacola" and wait orders.

Passed Assistant Surgeon G. E. H. Harman, detached from the "Pensacola" and wait orders.

Passed Assistant Surgeon J. M. Edgar, detached from the "Pensacola" and wait orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended March 3, 1888:

G. W. Stoner, Surgeon, detailed as chairman of board for physical examination of officers and candidates, Revenue Marine Service, Feb. 28, 1888.

F. M. Urquhart, Passed Assistant Surgeon, detailed as recorder of board for physicial examination of officers and candidates, Revenue Marine Service, Feb. 28, 1888.

P. C. Kalloch, Passed Assistant Surgeon, relieved from duty at Pittsburgh, Pa.; ordered to Marine Hospital, San Francisco, Cal., March 2, 1888.

P. M. Carrington, Passed Assistant Surgeon, relieved from duty at Marine Hospital, San Francisco, Cal.; ordered to assume charge of Service at Pittsburgh, Pa., March 2, 1888.

J. J. Kinyoun, Assistant Surgeon, granted leave of absence for twenty days, Feb. 28, 1888.

WHOLE No. 1620.] MARCH 17, 1888. [VOL. LVIII., No. 11.

PRICE $5.00 PER YEAR. SINGLE NUMBERS 10 CENTS. ESTABLISHED IN 1853 BY S. W. BUTLER, M. D.

PHYSICIANS' ANNOUNCEMENTS of Sale or Purchase or Exchange of Practice, or Books, or Instruments, inserted for two dollars first time, one dollar every succeeding time, space not to exceed one inch.

W. H. WALMSLEY & CO.

SUCCESSORS TO R. & J. BECK,

Manufacturing Opticians,

No. 1016 Chestnut Street, Philadelphia, Pa.

Microscopes,

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

CLEARING OUT SALE

—OF—

POCKET RECORDS.

We have on hand a small number of Pocket-Records prepared for the year 1887.

We would like to sell them, and in order to get rid of them, we will make the following offer; we will mail

A Pocket-Record for 30 Patients a week for 50 cents.
" " 60 " " 75 "

This is Less than the Books Cost Us.

There is nothing the matter with them, but we want to clear them out.

Drs. RANDOLPH & DULLES.

MALARIAL PARALYSIS, MOTOR AND SENSORY.

BY G. ARCHIE STOCKWELL, M.D., F.Z.S.,
PORT HURON, MICHIGAN.

It is unquestionably true that there is no group of morbid affections which possess wider scope, or greater claim to attention, than the so-called *malarial* diseases, since they pertain to all regions of the globe, the remoter portions of the frigid zone, perhaps, excepted. The obscure relations of malaria to other diseases are frequently proven by the presence of its germ; a germ that, pathologically affecting the portal system to the general derangement of the circulation and nutrition, manifests itself chiefly through the medium of the cerebro-spinal system, its especial predilection being the nerve centres. The latter circumstance, and the consequent tendency to association with puzzling, anomalous, and alarming symptoms, as in so-called pernicious and cerebro-spinal fevers and anæmias, gives especial prominence and interest to all maladies pertaining to this group, and a study thereof demands not only intimate acquaintance with the laws of neuropathology, but also of the toxic effects of the malaria germ upon nervous tissues.

With regard to the latter, the phenomena upon which the student or practitioner is required to depend, are uncertain, since they scarce ever manifest themselves twice alike, or as possessing like relations. The contracted vessels of the skin, and the rigors associated with the cold stage are evidence of stimulation of the vaso-motor nerves; while increased temperature, flushed surface, full pulse, and the dilated vessels accompanying pyrexia, exhibit tissue paralysis, both nervous and muscular. The splenic and hepatic engorgements, or the diarrhœas and dysenteries that are so frequently the sequels of profound malarial poisoning, are derived from dilated and paralyzed arteries, and consequently excessive flow of blood to enfeebled tissue. With such evidence, we need not be surprised at encountering also paralysis of voluntary muscles arising from like causes and phenomena.

All experience with malarial poison testifies to its exceeding subtlety and especially depressing effect upon the nervous system; and not to mention *cretins*, the inhabitants of markedly malarious districts are invariably described as "feeble of body and lacking in mind." Trousseau says the varied and peculiar symptoms exhibited by marked intermittents or malarias can be explained only by referring to the effect of a poison upon the nervous system; and Erb adds, referring to poisons as a class: "They cause lasting paralysis, as a rule, only when their action is slow and repeated, more rarely when they are acute; they cause the most varied forms of paralysis and paraplegia from simple weakness and paresis to complete paralysis, * * * * with or without disturbance of sensibility."

Unfortunately, malarial disorders are seldom regarded as presenting anything new or novel; nevertheless the knowledge that several cases of functional paralysis—by which title I include *paresis*, *parœsthesia*, *anæsthesia* and *analgesia*—have obtained grave prognoses at the hands of medical men to the unnecessary alarm of the patient, and that text-books universally ignore these paralyses as such *per se*, emboldens me to contribute in some measure to the subject.

At the beginning of my professional career I located in the city, in Eastern Michigan, which is still my home; and though it is

less malarious than most portions of the Lower Peninsula, I have from time to time encountered numerous cases of sensory and motor paralysis, which were, unmistakably, of malarial origin. Recently my attention has been more especially called to this matter by a number of cases occurring in the practice of my brother, the imperfect records of which, as obtained from him, are here presented:

Case I.—D. C., male, age 40, day laborer. First seen October 16, when he was found to have lost control of both legs and feet. He had been employed for some weeks as a stevedore at one of the lumber ports of Lake Huron, and latterly had worked much "over time." Ten days before he was taken suddenly with weakness across the bowels, followed by nausea and headache. These symptoms passed away in a few hours, and he returned to his work.

The second day following, he was again seized in like manner, the weakness being general, and being suddenly followed by loss of control of the lower extremities, which were cold, blue and covered with goose-flesh. After a few hours there was improvement, but the paralysis remained, though it was less persistent on alternate days, while on the intervening days the weak spells recurred. The bowels were constipated, as they had been for some weeks.

Physical examination revealed the temperature of the paralyzed extremities to be considerably below the norm, and that, too, in spite of the fact that they had just been removed from a strong mustard bath. Sensation was present only along the anterior aspect (over the spine) of the tibia, and over the most prominent points of both external and internal malleoli. Ordered 1.30 grammes (about 20 grains) of calomel and 0.02 (⅓ grain) of podophyllin, with quinine muriate, and camphor monobromide, to be taken immediately. This induced free catharsis, when quinine and euonymin were prescribed in generous doses, along with an aperient pill (nux vomica, belladonna and compound extract of colocynth) to regulate the bowels. From this time out there was no recurrence of weakness; sensation and motion rapidly returned; and, eight days after the first visit, the patient was standing upon his feet, with good control of his limbs. Recovery perfect.

The following five cases exhibit disturbance of sensation more or less complete.

Case II.—Mrs. W. N. B., aged 40, was seen on March 8, and found in a cold damp room, which was her usual sleeping apartment; what little heat was obtained came from a stove in the next room. The house stood upon posts, without wall or cellar, and the floor of the chamber was markedly cold. One window, heavily shaded by trees, opened from this sleeping apartment toward the north; and the ground everywhere, even beneath the floor, was low, wet and marshy. The patient had been a dyspeptic for three years, and her stomach was yet weak. She had no appetite; and but little taste. She had also a foul taste in her mouth on rising; aching bones and cold damp feet at all hours, in spite of applied warmth; and complained of being perpetually tired and irritable, and of sensations of chilliness and flushes of heat alternately, which were most marked in the morning between six and nine o'clock. At the time of the first visit she complained of intense pain in the epigastrium, apparently neuralgic in character. Physical examination revealed no abdominal engorgement, no enlargement of the liver, stomach, or spleen; while her tongue had a whitish-brown coat. For a day or two treatment was directed toward mitigating the more urgent symptoms, especially the sensitiveness of the stomach. Meantime the unpleasant sensations described continued to assert themselves with more or less regularity, and, at about the same period each day. Suddenly, after little less than a week had elapsed, and at the accustomed hour of *malaise*, disturbance of sensation occurred which caused no little alarm: numbness seized upon the forearms, hands, legs and feet, and apoplexy was feared by the family. This, however, gradually disappeared after a few hours, leaving only a slight prickling sensation. Immediately, about twenty grains of calomel was administered, and when its effects had subsided, antiperiodics, tonics, and alcoholic stimulants were ordered. The patient now began to improve, though with occasional relapses during the recurrence of damp, chilly weather, which invariably appeared in the morning, and were accompanied by more or less paresis and anæsthesia. As her surroundings were unfavorable to recovery, she was advised to remove to another locality as soon as possible. This advice was acted upon, with the result of rapid gain in health and strength.

Case III.—A. L. H., cabinet maker, aged 29, was etherized on February 27, to have a broken and carious set of upper teeth extracted. The operation was tedious and severe, and was attended by considerable, though by no means excessive, loss of blood. Four days later, at midnight, the patient suf-

fered from what was supposed to be a paralytic stroke; his arms from the elbows to the finger tips, and his legs from the knees to the toes, were totally devoid of sensation. At about 4 P.M. that evening he had experienced a weak and tired sensation, with a general feeling of numbness, which on retiring seemed to pass away; but about 10 P.M. he was awakened by a slight rigor, which was succeeded by decided anæsthesia of the extremities, and numbness of the palate and gums; the latter, as he expressed it, "feeling like large potatoes," though no swelling was visible. For a day or two he had suffered with anorexia, weakness, vertigo, partial amnesia, foul mouth, constipation, and general lassitude. His living room was over the bank of a sluggish river, the ground being such that at this time of year it was continually damp and beyond reach of the sun's rays. His pulse was rather quick, and somewhat weak; his pupils were larger than normal, but responded readily to light; his tongue had a light brown coat. For two or three days there had been recurrences of the "weak feeling" at about the same hour in the afternoon. Under alteratives and antiperiodics, iron and alcoholic stimulants, the "weak spells" and numbness were delayed in appearance until a later hour in each day, and became at the same time less marked, until they finally disappeared. Nevertheless, as there was constant tendency to recurrence, owing to the unsanitary condition of his surroundings, he was advised to change his residence. When this was done, convalescence became more rapid, and recovery was soon complete.

Case IV.—Mrs. J. G., aged 65, ill for two months, and greatly dispirited in consequence. Her trouble began with a severe attack of neuralgia of the right side of her head and face, which came on suddenly in the morning, the points of suffering being in the region near the supra-orbital, infra-orbital, and mental foramina. Subsequently followed anorexia, nausea, lassitude, eructation of gas, foul mouth on rising, brown tongue, sensation of weight in the stomach, occasional palpitation of heart, ostealgia, and cold extremities. These manifested themselves every forenoon, and were generally preceded by a desire to yawn, gape, sigh and stretch, succeeded by slight irregular rigors and flushes of heat. The neuralgia was followed, and at times supplanted, by loss of sensation in the painful regions, more particularly in the vicinity of the mental foramen; at the same time there was paresis of the legs and feet, and entire loss of sensation in those portions of the forearms supplied by the ulnar nerves. These symptoms were most marked in the forenoon, though they frequently continued through the day for days at a time. Usually, too, there was a slight rise of temperature and pyrexia in the afternoon, the thermometer on a few occasions registering 106°; though the pulse rarely reached 103, and exhibited no marked weakness. Her dwelling was in an imperfectly drained portion of the city. Her sleeping apartment was very small (9 x 12 feet), and on the north side of the house, with only one window, and it was imperfectly warmed by a stove in an adjoining room. The ventilation was execrable, and a cold current of air could always be detected along the floor to a height of twelve or fourteen inches. The treatment was practically the same as in the preceding cases, and the tendency to recurrence was obviated by removal to a more comfortable and convenient dwelling. This patient had suffered from paralysis agitans of the right side for some years, but the manifestations of this present malady did not differ from those observed prior to this attack.

Case V.—J. B., merchant, aged 50 years; residing fifty miles away. About April 1 he began to awaken in the morning with a foul mouth, coated tongue, headache and languor, which continued until late in the afternoon. At times he observed a throbbing sensation in the top of the head; again, he would be troubled with vertigo and dizziness, with constant gaping and sighing. He was also irritable—a condition quite foreign to his natural disposition. His appetite was at no time disturbed, or, if anything, it was increased, and he had no tendency to distress or irritability of the stomach. His bowels were constipated; and he had irregular rigors, followed by flashes of heat. He often had a prickling sensation at the vertex, as if his scalp were "asleep," invariably followed by a throbbing synchronous with the beat of the heart, which terminated in increased cephalalgia. He first consulted my brother on May 11. Examination revealed a coated tongue covered with thick whitish-brown fur, and moderate enlargement of spleen, but nothing further which could be deemed abnormal; and the microscope exhibited no deficiency or excess of white or red blood corpuseles. There had been no disturbance of the heart's action save when cardiac depressants were administered; these invariably increased the headache. His urine contained a slight excess of urates, and an abundance of indican,—the latter being found in all the cases. The diagnosis was malarial poisoning, though at the time nothing

could be learned of his surroundings to substantiate it; ultimately, however, it was learned that a wet cellar extended under the whole of his house and store. Under treatment he improved decidedly and rapidly, and returned home apparently well, but with the caution not to over-exert or expose himself, and to look out for a recurrence of the attack a week later. These instructions, however, were forgotten, and as the week drew to its close he was caught in a northeast storm and the following morning was seized with paralysis of both upper and lower extremities, and numbness in region of the right mental foramen, which last, after twenty-four hours, partially disappeared. This caused great alarm, as it was supposed to be the forerunner of apoplexy. For several days the numbness that followed the paralysis exhibited a tendency to increase in the forenoon of alternate days, at which time there was increased *malaise* and rise of temperature; and the seventh day from the paralytic seizure, he suffered a second. He now returned to the city for renewed treatment.

Owing to repeated carelessness his recovery was retarded. The temperature in no instance rose higher than 99°; and the pulse never exceeded 96, except under special stimulus or excitement. Hot alcoholic stimulants, hot lemonades, and wraps thrown about him, relieved the attacks of numbness, in part, by provoking copious diaphoresis. He had a great antipathy to mercurials and cathartics, and the humoring of his whims caused less satisfactory improvement than could be desired. But finally, a large dose of calomel was administered, which provoked copious green evacuations; whereupon the last traces of numbness disappeared, and complete recovery took place in a few days.

Case VI.—Miss E. H., aged 16 years, was seen June 1. One year ago last Spring, she was seized one Thursday at noon with numbness and complete loss of sensation in her upper and lower extremities, followed in the afternoon by neuralgic headache and slight fever. On eight successive Thursdays these symptoms recurred with occasional variations or additions and a loss of sensation in palate, tongue, and left side of the lower portion of the face, more particularly over the mental foramen; while enduring such attacks she could not pronounce certain words, more especially those well supplied with linguals. Her intellect was generally clear, and never more than temporarily dulled. Sometimes there was more loss of sensation in the left extremities than in the right, and on several occasions the left thigh was also involved. While these attacks lasted the sense of touch was so greatly in abeyance that prehension was often impossible, or at best accomplished only under the guidance of vision. Other prominent symptoms were: vertigo, ostealgia, languor, and tendency to amnesia, and to gape and stretch. After undergoing prolonged treatment at various hands without benefit, she recovered spontaneously with the advent of sultry weather.

When she presented herself for advice, twelve months later, she was suffering with a second attack, which began a week earlier than the first, and with headache, lassitude, and fever in the afternoon, followed by paralysis. One day the numbness would be more marked upon one side than the other, or perhaps wanting on the right side; once the left side of the mouth was paralyzed, the loss of sensation being most marked over the mental foramen. Variation of pulse and temperature were not marked, and sometimes wholly absent. Inquiry revealed the fact that she resided over a butcher's-shop, where large quantities of ice were stored for the preservation of meat; and the back room on the lower floor was frequently employed for rendering fats and other refuse. The case yielded readily to antiperiodics, and hepatic stimulants, the effects of which were materially assisted by the sudden invasion of warm, dry, weather and a "change of residence."

In addition to the foregoing cases of Dr. Charles Bliss Stockwell, I will mention one occurring twenty-four years ago in the practice of my father, Dr. C. M. Stockwell: A child six years old had suffered with intermittent fever for a fortnight or more; and was relegated to the care of one of the numerous dames infesting every community, possessed by a mania for dabbling in physic. It was suddenly attacked with hemiplegia, when a physician was summoned, and it made a rapid recovery under the exhibition of antiperiodics.

In reviewing the foregoing cases of functional nerve disturbance of malarial origin, it may be observed that the malarial poison produces various functional perversions of the nerves of the extremities, varying from slight coldness and numbness, on the one hand, to complete loss of both sensation and motion on the other. In five of these cases all four extremities from the elbows and knees, were involved; in one, the lower extemities alone; and in the other, one upper and one lower extremity. In two cases there was both motor and sensory paralysis. The regions over the mental foramen were involved in two cases, on the left side, and in

one upon the right. The tongue and palate were attacked slightly in one case and markedly in another.

Low, imperfectly drained surroundings, cold and damp weather, over-exertion, and worry, aid materially in the production of the malady just described, and also in retarding convalescence. Warm, moist or dry weather, on the contrary, facilitates recovery. All of these cases occurred in the Spring, late Winter or Autumn. As is a general rule with masked malarias the attacks, save in one instance, came on before noon, and invariably exhibited but slight elevations of temperature. The less the amount of fever the greater were the manifestations of the neuralgia; and the pulse differed little from its normal rate. The intellectual faculties were disturbed in but two instances, and by no means markedly so; however, in my own experience I recall three cases of complete, though merely temporary loss of memory, and one of deafness. Tenderness over the spine was rarely, if ever discovered, even by the most critical examination; and recovery was complete, including restoration of function and sensation in every instance.

After studying the different "Systems of Medicine" and works devoted to practice at my command—Niemeyer, Watson, McClintock, Tanner, Trousseau, Fothergill, Reynolds, Aitken, Flint, Pepper, Ziemssen, etc., I find nothing beyond bare statements that, in rare cases of malarial poisoning, paralysis *may* supervene; and a few remarks of Erb, quoting from Hertz (Ziemssen's Cyclopædia), under the caption of Intermittent Spinal Paralysis. The latter embraces the two cases of Maccario: 1. A woman suffered an attack of paralysis and anæsthesia of the extremities and tongue, two days after parturition; symptoms repeated in quotidian type for three days; yielded readily to quinine. 2. Male, 64 years of age, had a sudden attack of paralysis of the lower extremities and sphincters, but without loss of sensibility. The following day he had recovered sufficiently to void urine, and walk with difficulty, complaining only of general weakness. The third day paraplegia recurred, and on the fifth day he recovered.

Voluminous periodical literature, embracing a period of half a century, was also consulted, and with nearly as meagre results. In *Braithwaite's Retrospect* for 1857, Dr. C. Hanfield Jones cites two cases from Dr. McCullough: Both were members of a family residing in a malarious district, nearly all the members of which had suffered with intermittent fever of the ordinary type. These, however, were attacked with paralysis, one of the leg and thigh, the other of the arm, which disappeared spontaneously, with establishment of an ordinary quotidian intermittent.

Again, in a monograph devoted to functional nervous disorders, Dr. Hanfield Jones mentions the case of Mr. Stewart, an old Peninsular and Waterloo officer who was attacked with nervous pain in the head and hemiplegia of the left side. Power was lost, but sensation remained, though it was somewhat blunted. The pulse was 100, weak and small; and the intellect clear. An hour after the attack he had a slight rigor, followed by perspiration. The hemiplegia gradually wore off, but recurred, as slight attacks, at intervals, on alternate days during the following week. Under antiperiodic treatment, recovery took place. Dr. Jones mentions also the case of a man 20 years old, who was ill one month with "inflamed sore throat," after which paralysis supervened, the legs being weak and cold. He had no pain, no tenderness of spine; his sphincters were normal, his intellect clear, his skin cold, his pulse natural, his tongue white, his heart sounds normal, his urine healthy, but high-colored. His residence was wet and damp; no indication of disease of nerve centres. He recovered on the 28th day, under quinia, strychnia, mineral acids and porter. The phenomena of vaso-motor paralysis were well marked in the skin and in the mucous membrane; and it is conceivable that the vessels of the nerve centres were in a state of spasm, and that the paralysis depended upon nerve anæmia. The primary cause undoubtedly was a malarial miasm acting upon an average system.

Two more cases are noted by the same author in the *Lancet* for 1856, of which he says: "They appeared to be ordinary neuralgic affections of the upper extremities, peculiar only in this: that the motor nerves of the muscles were involved to a considerable extent, and not the sensory."

My own experience leads me to believe that malarial paralysis usually tallies more or less definitely with the history of ordinary intermittents; yet this is not always the case. I recall two cases of dengue or "break-bone fever," in which the prodromata and course closely resembled this disease. Another was at first mistaken for manifestations of heat-stroke; and still another, had positively no symptoms aside from the paralysis, which occurred and disappeared coincidently with an urticaria. Occasionally, too, the cases are prolonged and stubborn, yielding indifferently

to ordinary antiperiodics, but amenable to arsenic in *large* doses, strychnia, or oil of parsley. Marked relief is also had from diuretics, especially if there is a tendency to profound anæmic hyperæsthesia (neuralgia).

Before closing this paper let me call attention to the close analogy existing between malarial pyrexia, neuralgia, and functional paralysis, which accounts for the frequency with which one is replaced by, or merged into the other.

The essential phenomena of pyrexia, whether of malarial origin or not, are: Increase of temperature; derangement of nervous function; disordered secretion; and impoverished nutrition generally. No physiologist need be told that any one or more may preponderate, perhaps to the total exclusion of others. Derangement of nerve function may, and does, induce paralysis—and that, too, without accompanying fever—and they are frequently seen in acute maladies. Hence, their appearance without pyrexia, in malarial disorders, should be no cause for surprise. Fever is often present, but it is so moderate as to escape the attention of patient or attendants, and is discovered only by visits at unusual and irregular hours: in the malarial remittent of the young, the febrile paroxysm is almost invariably nocturnal. Again, fever may assert itself as a neuralgia only, the intimate connection of the two being shown by their amenability to precisely the same remedial agent. At times fever and neuralgia are alike replaced, or accompanied by some form of motor or sensory paralysis: paresis, paræsthesia, anæsthesia, or analgesia. Involvement of the vaso-motor nerves causes pyrexia; and the different degrees of involvement produce the different conditions of neuralgia and paralysis. This is a physiological axiom, in accordance with which we find Pepper describing loss of sensation as a sequel of pyretic action dependent upon disordered portal circulation and consequent indigestion, and C. Handfield Jones asserting that neuralgia is but a form of febrile paroxysm, "the morbid phenomena being determined by the part upon which the poison fixes." Romberg describes pain as a cry of the nerves for good blood; nutrition being but ill-performed, the nerves undergo a form of molecular alteration which constitutes pain. What is true of anæmic hyperæsthesia is equally true of paralysis. Damp, cold, malaria all act in precisely the same way, by deranging the molecular nutritive actions of the nervous structure, and so unfitting it to fulfil its functions.

There are several circumstances which strongly support this view, chief of which is: 1. The frequent co-existence of pain with numbness, especially in highly sensitive parts. 2. The difficulty of differentiating the condition which produces pain from that causing numbness—the action of cold, for instance.

"It is clear," says Dr. Jones, "there is no opposition between them; both are present together, and the anæsthesia commonly remains as the more permanent condition in the intervals of the paroxysms of pain, and even after they have ceased to recur." Now numbness or anæsthesia is evidently a failure of functional power; and of the same import is the occurrence of various degrees of muscular paralysis, or of paresis, paræsthesia, analgesia, etc., which may be, and are, associated with neuralgia, evidently as analogous affections of the motor and sensory nerves.

In this connection the phenomena of myalgia present an illustration of neuralgia, for here the intimate relation of pain to debility is most apparent; the sensory nerves of the muscles suffer because the associated motors are weak, and consequently whatever increases the debility, also increases the pain, and *vice versâ*. In many well-marked neuralgic affections, too, there is evident paralysis of the vaso-motor nerves at the seat of pain, and hence it is probable the sensory nerves are in like state. Again, the pain of a sensory nerve, and the paralysis of a motor nerve, may both be relieved by the same Faradic current. Finally, that a nerve which receives for its nutrition blood poisoned by malaria should be disordered in its functions and give rise to pain, is quite intelligible, since it is well-known that the general action of the malarial poison is chiefly paralyzing, as is shown by the fact that it causes weakening of voluntary power.

—The year 1887 will long be memorable in London for the extensive epidemic of this disease, which is still in progress, and for the successful part played by the fever hospitals of the Metropolitan Asylums Board in the treatment and isolation of cases. About the latter end of July the number of cases of scarlet fever in the Metropolitan Asylums Board Hospitals—which during the early part of the year had averaged between 400 and 500 at any one time—began seriously to increase. The number of cases under treatment reached a maximum of about 2600 in the middle of November, and is now undergoing a slight decrease. The type of the disease has been for the most part unusually mild, and the mortality correspondingly low. —*Brit. Med. Journal*, Dec. 31, 1887.

SUBMUCOUS AND SUBSEROUS FIBROIDS OF THE UTERUS, AND BONY DEGENERATION OF THE RIGHT OVARY. RECESSION OF THE INTRAMURAL TUMOR DURING TREATMENT. DEATH BY OBSTRUCTION OF THE BOWELS, FROM PRESSURE AND PERITONEAL INFLAMMATION.

BY ENOS T. BLACKWELL, M.D.,

CEDARVILLE, N. J.

On December 20, 1886, I received a note from the late Dr. Elliston R. Bateman, asking me to visit one of his patients, Miss B., and stating that she had been taken, about a week previous, with intense abdominal pain, swelling, vomiting and marked constipation. He suspected localized peritonitis and ovarian disease; and requested that I should examine carefully, with especial reference to disease of the right ovary. I saw her in accordance with this invitation, alone, Dr. Bateman being unable to be present. The following conditions were noted at that time.

Miss. B. is 48 years of age, and has missed her menstrual flux for six or eight months; the flow re-appearing in the latter part of last month, and again at the present time. On Monday night, a week since, whilst turning in bed, she felt as if something gave way within the abdomen; and the following day, Tuesday, she had pain in that region, which became very severe. The part was also exceedingly tender. She had great thirst, nausea and vomiting. Her tongue was heavily coated, and the bowels obstinately constipated. The tenderness reached from the hypogastrium to the umbilicus, extending widely on each side the middle line. The affected space was hard, tender, dull on percussion, and had a well-defined border or edge. In the right iliac region is a tender spot, the size of an orange; distinct in its boundaries, and separated from the enlargement before described.

There is no fluctuation in either region. The pulse beats 112 per minute. I prescribed liberally of quinine, and alternated with laxative doses of calomel. A suitable external applicatian was also made. December 21, 1886. On this day, I again visited the patient in company with her attending physician. She sweated freely during the night; and her tongue is cleaner and her manner brighter. She has had a free evacuation of the bowels, and has eaten some toast. Upon making an internal examination, the vagina was found soft and extensible. The os is diffused—does not project any whatever, and just admits the uterine sound. It penetrated about one and a half inches; but could be introduced no further, though persevering efforts were made in all directions. The tumor in the hypogastrium seems to be a fibroid, attached to the posterior part of the uterus. The enlargement in the right iliac region is probably of the same nature, as no tenderness could be discovered in the ovarian region on internal examination. She was ordered the following:

℞ Ammonii chlor.....ʒj
Spt. ammonii arom.....fʒj
Extract. ergotæ fl.....fʒvj
Aquam.....ad fʒiv
M. S.—Teaspoonful three times a day.

January 22, 1887. Miss B. has an excellent appetite; her bowels are regular, the tongue clean, and her menstrual function upon her. The mid-tumor projects obviously forward. It reaches exactly to the line of the umbilicus—perhaps a trifle advanced beyond the point reached a month since. The tumor in the iliac space appears less prominent than at that time. She tolerates the medicine well, and is to continue as follows, viz.: 30 drops fluid extract of ergot after each meal, and 3 grains chloride of ammonium, in tablet form, before each meal. She continued these medicines for some time, assuring me whenever I saw her, that no increase in the enlargement had occurred; and, finally, believing that her trouble was at an end, left them off. She became very active in household work; and after wearisome labors, and some indiscretion in diet, she was seized, September 6, of this present year (1887), with severe colicky pains in the line of the transverse colon, and great nausea. To antagonize these symptoms, she was given morphia, salicylate of sodium, and carbolic acid: for the accompanying constipation she had 2 grains of calomel every two hours. On the day following, September 7, she, in addition to the mercurial, took podophyllin; the former medicine having failed to produce a movement. On September 8, she had podophyllin, leptandrin and compound extract of colocynth, in pill, with the extracts of belladonna and nux vomica. On the supposition that the morphia might retard action, chloral hydrate, 5 grains, in solution as required, was substituted. On Friday, September 9, the bowels still remaining unrelieved, croton oil, one to three drops, were given every hour, for three or four times in succession. This was omitted during the night, and resumed on the morning of the 10th. There was no movement downward

at the end of two or three hours, but a copious ejection of stercoraceous matter occurred by the mouth; and was repeated once or twice during the forenoon. She had been receiving enemas, at first simple, afterwards the more powerful, containing oil of turpentine; and, finally, croton oil was added. In the latter part of the day she received two quarts of cold water by enema; but no feces followed any of the procedures. Dr. Ephraim Bateman was now called in consultation, who advised a blister to the prominence in the right side of the abdomen, which was applied. Laparotomy was mentioned; but I did not understand that it was recommended. There was at this time a great deal of tympanites and obscure tenderness. She continued to take the chloral as before; and it gave her fair relief. The blistering plaster drew well; but the patient's abdominal trouble remained unchanged. She, however, manifested a desire for food, which she had heretofore declined. She took at long intervals about two ounces of strong beef-tea, and the same amount of infusion of coffee. She declined any attempt at alimentation by the rectum. The pulse at this time had a daily period of acceleration. It continued to quicken, and reached 118 at this day's observation. On Sunday, September 11, the condition of the patient was unchanged. On the morning of September 12, Dr. H. W. Elmer was called as consultant. At his suggestion a prominent coil of intestine was pierced through the abdominal wall by a hypodermic needle,and some foul gas escaped; but not enough to greatly change the aspect of the abdomen, which was tightly distended, showing several distinct lines of elevation, answering to the various coils of intestine beneath. By his advice, a specialist was called, with a view to a possible laparotomy. In the afternoon, from three to six o'clock of this day, the patient suffered great pain about the umbilicus; her nails were blue, and she lay in a cold sweat. Her pulse at 8 P.M., marked 122.

September 13. Miss B's fever continues much the same, pulse 122. In the evening she had mild delirium.

September 14. The patient has been fairly comfortable during the night, awaking frequently, but soon falling asleep. She takes liquids—table-tea and beef-tea. The pulse rate is 108.

September 15. Drs. M. Price and Burns, of Philadelphia, arrive at 11 o'clock A. M. The patient's condition being desperate; by their advice laparotomy was decided on, as a possible chance of relief to the strangulated intestine. Dr. H. W. Elmer, of Bridgeton, arrived at 1 o'clock P.M., and all things being ready, the patient was placed upon the operating table, after being fully anæsthetized with pure ether. The line of incision extended from the pubes to the lower boundary of the epigastrium. The tumor when reached was found attached by broad adhesions to the abdominal wall, and by many strong bands of false membrane to adjacent loops of intestine. Much time was occupied in breaking up these firm ligaments, and when at length the tumor was turned out, its uterine attachment, a slender, cord-like structure, was secured by a silken ligature; and, when severed, was allowed to drop into the abdomen. The intestines were of a very dark color, and the tympanites so great that much difficulty was experienced in confining them within. They had been continuously drenched with hot water during the operation, and the containing cavity mopped out with the sponge. When thoroughly cleansed a drainage tube was inserted, and the wound closed by the interrupted suture. The line of incision was freely dusted with iodoform, the parts covered with absorbent cotton, and covered in with a broad bandage. The patient's extremities were very cold at the conclusion of the operation, which lasted for an hour, and her circulation was very low. She was placed in bed, and well covered; bottles of hot water were freely applied about her person, and the subcutaneous injection of brandy, resorted to in the later stages of the operation, were continued. No blood to signify was lost in the removal, but the shock to the system was profound. Warmth returned to the body, but her strength failed, and her death occurred within the second hour after the conclusion of the excision.

Autopsy held September 17, at 3 o'clock P. M.: Dr. H. W. Elmer assisting.

On opening the body at the incision made in the surgical operation, the intestines presented themselves dark and very tympanitic. At the points from which they had been severed from the tumor, there was general roughening, and the remains of many strong neoplastic bands. From these ruptured parts there was sufficient oozing of blood to give them a raw appearance. On tracing the intestines throughout, there was found some thin excrement, but no occlusion. The uterus was thickened and contained a submucous fibroid about two inches in diameter, and was somewhat flattened antero-posteriorly. This was blended with the muscular structure in front and to the left, while posteriorly

and to the right it projected slightly from the inner wall of the uterus, and was there easily separable from it. Its tissue was of a dusky white color, very dense, and apparently destitute of blood-vessels. The cavity of the womb was somewhat enlarged, being estimated to hold one ounce of fluid. At the right superior angle of the fundus uteri was found a pedicle one and a-half to two lines in diameter and half an inch long, with the ligature as placed during the operation. This was firm and fibrous in structure, and occupied the position assigned to the Fallopian tube. About an inch beneath this there was a protuberant nodule, flattened and ovoidal in shape, and measuring in its horizontal, or greatest length, one and a half inches, and one and a quarter inches in the thickness. It was slightly embossed externally, and covered with a smooth, shining membrane, the peritoneum. On section it grated harshly beneath the knife, and the tissue on examination was found to consist largely of bone.

The uterus and accompanying tumors, when examined critically, were found to be as follows: The length of the former, exclusive of its neck, which is much thickened, is about three inches, and its thickness two and a half inches. Having been opened posteriorly in its axial line, the tumor presents within the muscular coat, with which it it closely blended in front and to the left. Posteriorly, it lies within the mucous lining, with which it is loosely connected. It projects very slightly into the cavity. Beneath the pedicle, already described, is the calcified tumor mentioned. It measures one by one and a half inches, and has a broad and thick uterine attachment. The tumor is whiter than the mural one—a light mulatto color. The calcareous deposits within appear to be in separate and distinct points, and concentric, as if precipitated from the inner walls of previously existing cysts. In the centre of one of these annular aggregations is a shallow cavity, which admits the button of a large probe. There can be no doubt, I think, that this tumor, from all its characteristics, is the right ovary which has undergone bony degeneration.

Attached to its anterior face, there is an enlargement the size of a chestnut, having also an appearance of concentric formations; but no bony structure. At the posterior inferior part of the womb is a tumor the size of a large hickory-nut, smooth externally, and covered only with peritoneum. It is easily separated from its bed by enucleation.

None of the tumors seem to have exercised any unhealthy influence on the patient's system, except the one removed by the operation. This had at different times, set up peritoneal inflammation causing effusion of plastic material, and resulting in the formation of adhesions and false-membranes, whereby the bowels were bound down, and securely held. The obstruction may have occurred by some sudden change in the position of the tumor, by which it was caused to press upon the bowels; or, by altering the relation of the constricting bands so that strangulation ensued. It may easily be inferred that peristalsis had been in constant liability of interruption from this cause; the great wonder being that interference with digestion was so long delayed.

The uncertainty of the location of the obstruction, and the great probability of complications from adhesions, the result of former inflammations, together with some family considerations, are mentioned as reasons for not advising early operation. That it could have been successfully performed at any time, in view of the extent and strength of the adhesions binding the various structures in such close union, can scarcely be maintained beyond controversy.

THYMUS VULGARIS IN THE TREATMENT OF WHOOPING-COUGH.

BY J. B. JOHNSON, M.D.,
WASHINGTON CITY, D. C.

Few diseases are confronted by so large a list of remedies as pertussis. Its antagonists are arrayed in a solid column of thirty-six internal remedies, and nineteen by inhalation, and yet the disease does not evince a docility that renders it tractable to any great extent. When the disease terminates in health, the result is always satisfactory, but satisfaction has not always followed the use of the multitude of remedies offered by their respective advocates to control the disease; for in defiance of the influence of medicines proposed for its cure, it obstinately and contemptuously goes on, as it may elect, to the fourth or twelfth week of duration.

Rational medicine teaches that when therapeutics cannot control the duration or course of a disease, the next duty of the physician is to ascertain and select those remedial agents which present the greatest power to modify the force of the disease, and thereby render its presence tolerable and its continuance comparatively sufferable. When this end is attained in the treatment of a malady that has a given course to run, these remedies have accomplished all that a reasonable

expectation can demand; and the comfort of the patient is not only conserved, but the efficacy and power of such remedies are vindicated.

Those who have never used common thyme in the treatment of whooping-cough, may smile when I say that my experience in its use has encouraged me to such an extent as to say, that of all remedies I have used for the alleviation of this disease, a decoction of common thyme has given the greatest satisfaction. The simplicity of its preparation, its mildness of action, and peculiar sedative and anti-spasmodic effect in controlling the violence of the paroxysms of cough, is most astonishing. The little sufferers take the decoction without the slightest hesitation; and the benefit which they derive from it is as prompt as it is remarkable. It only needs a trial to establish it as the remedy, *par excellence* for pertussis. It reduces the paroxysmal character of the cough, and renders the disease milder in its force, and shorter in its duration. It diminishes, in a peculiar manner, that inflammatory condition of the mucous membrane of the glottis and the air tubes, which, in this disease—more than any other with which mankind is affected—invites reflex spasm. In the accomplishment of this object, the danger and liability to complications is very much lessened, and the disease rendered comparatively harmless through a marked diminution of the tracheo-bronchitis, which is always to a greater or less extent its constant attendant during the two stages of the disease.

The first stage is called the catarrhal; but this is sometimes absent. When present, however, it lasts about two weeks, and is then succeeded by the second or paroxysmal stage, which varies in duration from four to twelve weeks; and is very much influenced by the constitution of the child. Complications involving the head and chest are always to be expected where the lungs have been rendered unsound by tubercular deposits; and danger always attends whooping-cough when it attacks a child whose constitutional powers are weakened by scrofula. When complications do occur, they should be carefully watched.

In my treatment of this disease, I require my little patients to wear flannel—red or white—next to the skin, and be kept in a room well ventilated, the temperature of which should be kept at night, as well as during the day, at about sixty-five degrees in the winter season. They are not allowed to leave this room until restored to health. I direct an ounce of common thyme to be put into one pint and a half of hot water, and boiled down to one pint, then strained and sweetened well with either honey or sugar. In this manner, it is made pleasant to the child. To infants I order one or two teaspoonfuls to be given regularly every hour or two, and to children a tablespoonful every hour or two during the continuance of the disease. Should auscultation reveal much inflammatory action of the bronchial tubes or lungs, I usually add two drachms each of iodide of potassium and powdered chlorate of potash, to each pint of the sweetened decoction, and direct it to be used in the same manner as the simple decoction. Under the influence of this treatment my little patients pass through attacks of whooping-cough with astonishing ease and comfort, and only on rare occasions, have I been compelled to use any other medicines. This treatment is greatly aided by a prudent attention to diet, which should consist of milk and farinaceous foods.

CHOLERA GERMS DESTROYED BY AMMONIACAL GASES.

BY J. B. CRANDALL, M.D.,
STERLING, ILL.

I have the honor to give a brief note upon the subject of "Epidemic Cholera," as it appeared at Fort Dodge, Kas., in the summer and autumn of 1867. The fort is situated upon the upper Arkansas River, near the present location of Dodge City. The garrison was composed of a batallion of the 3rd U. S. Infantry, troop B of the 7th U. S. Cavalry, and quite a large force of civilians. In July, 1867, a detachment of colored troops, on their way to New Mexico, encamped on the river bottom near the fort. The moving column lost some of their command with cholera along the line of the march, and one died while encamped for the night near us.

Surgeon Chas. DeGroff and I took all the precautionary sanitary measures within our power to keep the cholera out of our command, but the second day after the colored troops had left a man who had visited the encampment was taken down with cholera, and in less than a week we had a dozen cases on hand. The rapidity and fatality of this dreaded disease had a depressing effect upon the most of the troops, and caused a stampede of many of the civilians and quarter master employées of the post.

DeGroff was soon prostrated with nervous fever, so that the whole care and responsi-

bility for the sanitary condition of the troops, employées of the post, and the entire management of the hospital department fell upon me. The first thing done was to move the sick men from the bottom to tents on higher ground; and to have them scattered as much as possible. Reliable nurses were so scarce that some—who proved most proficient—were taken out of the guard house; even criminals were released and were put on the volunteer force as nurses, with the understanding that if they were faithful and survived, their punishment would be mitigated.

The epidemic was at its height during the middle and latter part of August, and continued with slight interruption during the months of September and October. We had showers of rain during the warm season, but they did not refresh us, as the ground was so hot that as soon as the rain struck the earth it generated a hot steam which would almost suffocate a person obliged to inhale it. Most of the cases of cholera were taken suddenly, without premonitory symptoms, with cramps in the stomach and bowels; with a rice-water diarrhœa; and with continuous vomiting of about the same character. The blood seemed to cease to circulate in the extremities; the hands and feet got cold, and this coldness traveled towards the center of circulation, and as soon as it reached the heart the patient would die. Many of them died in less than eight hours from the time of first symptoms of invasion. The only rational plan of treatment gathered from this experience was to keep up the circulation in the extremities. This was most successfully accomplished by constant and continuous friction with the bare hands of some strong attendant. Small powders of morphia were given at short intervals to quiet the pain, and small bits of ice to allay thirst. No liquid medicine was retained for the first twelve hours. If we could keep a patient out of the stage of collapse for twelve hours our prognosis was generally favorable, as most of such cases survived and were ultimately cured. In all classes during the cholera epidemic there were some eighty-five cases with twenty-eight deaths.

One singular feature of this epidemic, developed during its rage, is worthy the serious reflection of scientists, as it may lead to as valuable results as did the discovery of vaccination. The feature of which I speak is, that Troop "B," 7th U. S. cavalry, was exempt from the cholera, while the infantry, the quarter-master's employées, the civilians, as well as the officers, and those living on ranches for a radius of seventy-five miles about the fort, were brought in for treatment. The fact that the cavalry troop was exempt from disease was not attributable to the choice of location of ground, for it was on the same level with the infantry quarters and not more than a few hundred feet distant.

The true explanation I believe to be as follows: At the time when the cholera epidemic prevailed the post was not completed, and the men slept in a stone stable with their horses; and it seems to me reasonable to believe that the cholera-germ was neutralized or rendered inert by the action of the ammoniacal gas arising from the decomposed urine of the horses. And it seems to me a practical benefit might be obtained from this experience if in case of a future cholera epidemic, we were to adopt the customs of the Arabs in this respect, or to spray our homes liberally and often with spirits of ammonia in order to destroy or prevent the propagation of the deadly cholera-germ.

MUSCULAR RELAXATION THE CAUSE OF SLEEP.

BY G. W. FUREY, M.D.,
SUNBURY, PA.

Among the factors contributing to wakefulness, muscular contraction and relaxation are most important. In fact, so long as there is any considerable contraction of the voluntary muscles, there can be no natural sleep, and almost complete relaxation of them is necessary to the production of sleep, this being in my opinion the active *cause*, and not the *effect* of sleep. It seems to me clear that the slowing of the venous circulation suppresses or suspends the activities of the nervous centres sufficiently to permit of sleep. Let us look at a few reasons for this belief. The propelling force exerted upon the venous blood by the heart's contraction, as well as by that of the arteries, is at most merely nominal, owing to the intervention of the capillary system, against which it is expended. Then, as all will admit, there are other agencies than the action of the heart in maintaining the flow of blood in the veins. The channels for the return of the blood from the extremities are peculiar, differing from the arteries as to numbers, situation and mechanical construction; being situated generally between the muscles, supplied with valves, and averaging two or more in number to each artery. Now the occasional or continuous contraction of the muscles exerts a pressure on the veins, which, owing to the presence of the valves and the

passive nature of the veins, propels the blood onwards to the heart. Sleep depends upon a diminution in the quantity of blood circulating in the brain. Every one has noticed the tendency to drowsiness after meals, and the sleep of drunkenness is at least partly due to paralysis of the arterioles and muscles of the body in general, which renders the general circulation sluggish. Determination of the blood to the organs of digestion after eating accounts for the after-dinner nap, and all students can bear witness to a relative clearness of intellect when these organs are at rest. All careful observers must have noticed the instinctive disposition to walk the floor, to clench the fist, or to perform some like contortion during forced or violent intellection. You who read this have doubtless often laughed at your friend nodding in his chair, and have noticed his inability to sleep until his chin had fallen forwards, and the book had slipped from his relaxing grasp. Did it ever occur to you that *gaping* is only an automatic governor to restore waning energy and wakefulness by simply accelerating the circulation? If you are very drowsy, as you sit in your office reading this, just lay it down a moment and take a good "stretch." What has happened? You have pumped blood from and to the brain. You are awake again. It is not possible to sleep while one's fist is clenched, nor while any considerable amount of muscular contraction exists. One is usually awakened or set to dreaming by *the movement* provoked by any noise or external agency. The sluggard's yawn does not suffice to fully awaken him, but if he be pulled out on the floor he will be "wide awake." In that state of exquisite miserableness called nightmare, in which the temporary cerebral depletion is sufficient to produce a mental shock and motor paralysis, and the most vigorous efforts of an only partially absent will-power are totally inadequate to break the spell, it is only necessary, in order to throw it off, to be able to contract the flexor muscles of the little finger, and restoration to wakefulness is the result. Usually, in order to sleep well, a certain amount of preparation is required. One will naturally choose an agreeable place, then assuming the most comfortable position, allow the limbs to arrange themselves, the eyes to close and sleep to supervene. What has happened is simply this: The veins of the body having been relieved of a great amount of muscular pressure, become a general receptaculum of blood, which is drawn off from the nervous centres.

You will ask how can this theory be reconciled with the peculiar conditions obtaining in somnambulism and nightmare, and especially why the movements made in sleep-walking do not awaken the walker? I cannot do so, for the reason that we are not possessed of a *rationale* of somnambulism. And, again, it is in no wise the condition we are considering—"Natural Sleep." But if we apply the theory we have been considering as the cause of sleep to nightmare, it will aid us very materially in understanding a very probable cause of that distressing and dangerous affliction of humanity. You are aware that one is much more liable to an attack of nightmare while lying upon the back, especially if he have gone to bed soon after eating a hearty meal. This is owing to the fact that the weight of the stomach, while lying in this position, opposes, by its unnatural pressure upon the ascending vena cava, the free return of the portal circulation, sufficiently to produce anæmia of the brain. This may be to such an extent as will result in death.

Hence I assert that, whatever the ultimate phenomenon may be, the proximate cause of natural sleep is *muscular relaxation.*

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, February 22, 1888.

W. W. Keen, M.D., in the chair.

Dr. W. W. Keen read a paper on

A Case of Macewen's Operation for the Radical Cure of Hernia, followed by a Speedy Return of the Hernia.

I think it important to report failures as well as successes. Macewen's operation, also, has been so generally successful that it is the more important to report the failure of this case as the immediate result of the operation seemed to promise a cure; but, as you will see, the hernia has quickly reappeared. For the notes of the case I am indebted to Dr. Lambach, the Surgical Resident.

The patient is a man thirty-two years of age, a fresco painter, but for some time at work dredging oysters. When seventeen years old he first noticed a right oblique inguinal hernia, for which he wore a truss for a year and then laid it aside. The hernia remained cured for thirteen years. A year ago, while at work dredging for oysters, the hernia returned, and descended into the upper scro-

tum. He entered St. Mary's Hospital on the sixth of January, 1888, on account of the disterss and inability to pursue his occupation. The operation was done on the 13th; on the fifth day I removed five of the nine external stitches, and on the twelfth day the remaining four. There was no pus at any time. The highest temperature was 100.2°. He had then two chills, the first on the fifteenth day, his temperature rising to 103°; but as there was no evidence of suppuration, as it yielded promptly to quinine and arsenic, and as his occupation had exposed him to miasmatic infection, we were justified in attributing this to malaria. He was kept in bed for twenty-nine days—*i. e.*, until February 11th. At this time I examined him, and found the hernia perfectly cured. He was then allowed to get up, a spica and compress being applied. Examining him yesterday (February 21), I found the hernia had returned, with, however, one gain—at the time of the operation the external ring was very large, requiring four double sutures. Now it will only admit the point of the index finger. Moreover, he is exceedingly comfortable; so much so that I doubt if I can persuade him to undergo another operation.

The steps of the operation I will illustrate on this model:

An incision was made over the site of the hernia to its lowest point in the scrotum. With the blunt end of the scissors and the finger, the sac was then dissected from the surrounding parts, care being taken to leave no attachment to the spermatic cord. The index finger then was passed within the abdominal wall, and the peritoneum was dissected for half an inch around the circumference of the internal ring. A moderately stout ligature of chromicized catgut was tied to the lower part of the sac, and a series of stitches taken from the lower portion of the sac to its mouth. This stitch, by means of Dr. Ellwood Wilson's curved trachelorrhaphy needle, was then passed through the abdominal wall from within outward at a point a half inch above and external to the ring, the skin being drawn upward and outward so as to allow the stitch to emerge through the abdominal muscular wall, but not through the skin. The traction was made on this stitch, thus puckering up the sac, which latter was drawn through the ring and rested against the inner surface of the abdominal wall to become adherent there, closing the hernial opening by a firm pad. The stitch was then carefully secured in place. The external ring was then closed by four double stitches of choromic catgut, passed from side to side. I was extremely careful in denuding the inner surface of the abdominal wall to get a large raw surface at the internal ring, so as to gain firm union at that point; and the patient was kept on his back for four weeks; yet it gave way a few days after letting him up.

I shall repeat the operation if he is willing.

Dr. H. R. Wharton said, in opening the discussion, I have no personal experience with Macewen's operation for the radical cure of hernia, but I have seen two cases in which Agnew's operation was employed, and three or four in which McDowell's method was resorted to; these are subcutaneous operations, and do not compare with this open operation in thoroughness. The immediate results seemed good in the cases referred to, but in a short time the hernias were down again. Recent reports from England, though still too recent to allow us to estimate the permanency of the cure, are very encouraging. As to Macewen's operation, I think it one of the best that has been proposed, and if any radical procedure is to be undertaken it seems to promise the best results. Of course, any operation is more apt to be successful in children than in adults.

Dr. C. W. Dulles said: I would like to ask Dr. Keen if any appliance other than the bandage was used after the patient began to go about. The hernia looks as if it had been down some time, and not as if it had descended recently. I think it would be best not to trust solely to the strength of the tissues for a little while after these operations. There is a point in the mechanics of hernia which I have noticed, and which I have not seen described by others, and that is, that a patient with inguinal hernia usually has a pendulous abdomen. I was curious to see if the spare patient of Dr. Keen's would follow the rule, and I saw that he did. I may lay too much stress upon the matter, but I believe that the best appliance is not one which makes pressure over the ring alone, but one which corrects this abdominal outline, and changes the direction of the thrust of the intestines from one at right angles to the plane of the hernial opening to one parallel to its plane. The diagram which I draw on the blackboard illustrates what I mean. Such an abdominal supporter as women wear would answer the purpose, and I believe that it would add to the chances of permanent success after operations for the radical cure of hernia.

Dr. Keen said: Of the cause of failure, I can only say that apparently the reparative power did not suffice to obtain adhesion of the sac

to the abdominal wall. Why, unless the two chills referred to had some influence, I do not know. The usual practice of those who have had a large experience with these operations has been not to use any truss. I must take exception to Dr. Dulles's diagram. He is right as to the shape of the abdomen, and in correcting it to a more oblique outline, but the pressure will always be at right angles to the abdominal walls anteriorly, and not as he has it here, down into the pelvis. That would, however, correctly express the direction of the rebound. As to the exact time when the hernia reappeared I cannot say. When I examined him, February 15, four days after letting him up, it was not there. I did not see him again until February 21, when I found it had reappeared. I shall not wait long before repeating the operation. He wants to be earning wages, and I do not want to burden the hospital with any patient longer than necessary. Any danger will have passed over in a week or two, and I will then operate if he consents.

Dr. Dulles said: When we bear in mind the comparatively mobile state of the contents of the abdomen, we must see, of course, that the intra-abdominal pressure is exerted in all directions, and we might draw any number of arrows to indicate it; but there is only one direction of "*thrust*," which is the resultant of all the lines of pressure; and by supporting the abdomen, as I suggest, by a firm and comparatively unyielding support, we turn the direction of that thrust into a line following the axis of the pelvis, and take it off the ring.

Dr. Wm. S. Stewart read a paper on

An Improved Obstetric Forceps.

It is not my intention to consume the time of this Society by giving a history of the origin of the use of the obstetric forceps, nor to enter into a general discussion of its merits or demerits. I take it for granted that there is a large majority admitting their necessity, and the great benefit they are to the lying-in patient. Therefore, I will content myself in endeavoring to point out the advantages of having parallel handles, so that the application of either blade first can be made at will, as the exigencies of the case may require. It is in order to meet this necessity, which I have more than once experienced, that I have the honor and privilege of presenting for your consideration an instrument which will demonstrate its superiority, and consequently can be relied on in almost any emergency.

The improvement is not restricted to any special form of blade, but can as readily be applied to the straight as to the curved, its use being equally effective with either form. The first object, for which I was most solicitous, was to be able to have an instrument which could be used readily in presentations where it might be desirable to apply the second blade first, as sometimes in the second position of the head when jammed into the cavity of the pelvis and rotation to the antero-posterior diameter has been prevented by a narrow, contracted passage. In all such cases there will be no difficulty in applying and adjusting the first blade; but, occasionally, it is impossible to apply the second in this condition of the presentation, the only remedy being to reverse the order by applying the second blade first, running the risk of injury to both mother and child in the recrossing of the handles, in order that they may be locked before making traction. This we have overcome by having the handles made parallel to each other, without overlapping, as in the ordinary instrument. Each handle has its own independent lock, the two being connected by a plain bar, which will admit of adjustment no matter which blade is applied first.

To overcome the danger of slipping, and to secure the grasp on the fœtus, it was necessary to devise some method of reversing the direction of the handles, in order that traction could be applied. To accomplish this a double lever was devised, one part on each handle, and each working on the same pivot or fulcrum; to this the traction is applied, resulting in a power perhaps superior to anything we could have expected. The compression to the fœtus is no longer in propotion to the power in the grip of the hand applied to the instrument, as in the cross-handles, but is regulated simply by the resistance to be overcome, and beautifully illustrates the mathematical relationship between the force and the resistance; consequently, all fear of the slipping of the instrument is obviated, and the only force that is necessary to be applied is for the delivery of the fœtus, serving at the same time for compression and traction. The compression, however, is controlled by a shoulder which is made on the toggle-joint, preventing any risk to the child, and its limit corresponding to the position of the blades of the cross-handled instrument when the handles are in apposition.

Should there be any irregularity of application, and consequent difficulty in locking, we have devised a coned hub with a winged nut, which, though the handles may be at an angle of twenty degrees, enables us to adjust them accurately.

The advantages of this improvement, as experience has demonstrated, are summarized as follows:

First. The application of either blade first.

Second. The impossibility of the slipping of the blades when properly applied.

Third. Moderate and even compression, the degree of compression being regulated by the amount of resistance.

Fourth. Greater facility for making traction.

Dr. Longaker: The only advantage of this modification of Dr. Stewart's, is that the forceps is not so likely to slip. This is due to the parallelism of the blades, which is maintained even though the blades be not on opposite sides of the child's head, and in very large heads where it is difficult to recross the handles. There is in existence another device for the same purpose, a very simple one, a mortise lock at the end of the handle. Personally, I think the forceps introduced by Sir James Y. Simpson cannot be improved upon.

Dr. Packard: I ought, perhaps, to speak with some diffidence on obstetrical matters, as my practice in that line has of late years been but limited. Yet I cannot but recall the teachings of Professor Hodge, and the extremely practical instruction given the students of my day by Dr. Joseph Warrington, which found abundant confirmation in my experience. We were taught that the forceps should never be applied unless the os uteri was dilated or dilatable; that they should be introduced with the utmost gentleness, the surface of the child's head being the sole guide; that ready locking (and no force was ever to be used to effect this) was the test of proper application; that under no circumstances was any leverage to be exerted by means of the mother's tissues; that the left hand of the operator (applied at the lock, the tip of the forefinger against the child's head, to detect any slipping of the blades) should be the fulcrum, the instrument being then used as a double lever, so as, by a gentle swaying motion from side to side, to coax the child's head through the passage. This side to side movement was strongly advocated afterward by the late Dr. Albert H. Smith, whose experience and authority in such matters must be conceded.

Under all circumstances, except in certain abnormal positions of the child's head, the blades were to be applied with their long axes parallel with the occipito-mental diameter; and they had to be accurately opposed to one another in order to lock. Now, it seems to me, in the light of my own experience, that the difficulty of recrossing the handles ought not to be such as to render a special mechanism needful in order to avoid it. And I cannot but think that the deviation of the blades from parallelism, however brought about, involves danger.

When the mother's forces are inadequate to effect delivery, I think the time has come to use the forceps; and to obviate the necessity of a long-continued grasping of the handles, they may be tied together with a handkerchief, or with any other convenient band, as soon as the blades are accurately applied to the head. The compression so made is often necessary to the delivery; and on several occasions I have myself felt the bones of the head give way under the grasp of the instrument, but the mother was unharmed, and the children lived. As to forcible traction, I have heard of the child's head being torn off; I have several times seen a strong man brace himself with one foot against the bed, and apply his whole power to drag the child from the mother. In one case I have known this practice to result in the tearing away of part of the cervix, laceration of the vaginal wall, and permanent damage to the mother's local and general health. In the old style of forceps—and the Hodge pattern has always seemed to me the best—we had in each blade, used singly, a vectis; in one handle a blunt hook, an instrument often of great value; the other was a sharp hook, covered, when not in use, with a steel cap screwed on. Such a combination of instruments, which is very convenient in a practice involving long distances, cannot be, or at least is not, offered in the forceps presented by Dr. Stewart.

Dr. George E. Shoemaker: While this instrument is, no doubt, safe in Dr. Stewart's hands, it might not be so in those of others. That toggle-joint is a very powerful mechanical appliance, and the "shoulder" does not limit its action until the blades are quite close together. A moderately large head would not let them get so near together, and a very violent and harmful compression would result from even moderate traction upon the handle.

Dr. Stewart, in closing the discussion, said: In reply to the first speaker, among the original forceps as represented in the older works, were those with parallel blades, but I do not know of anything like this instrument. Of course, I do not claim all the credit of this invention, but share it with the instrument maker, who carried out my ideas. I was induced to have such an instrument made because of a number of complicated cases,

which came under my care, especially a difficult one in which I was called to assist a friend, who had been trying all night to get on the second blade of the forceps in a very narrow pelvis, where the child's head was jammed (in the right iliac region), and would not rotate. I advised using the second or female blade first, which we did with precaution in recrossing the handles, and the delivery was speedily effected. I am not anxious to use forceps or to make lacerations. My rule is not to apply instruments as long as there is any rebound to the labor.

There need be no fear of the toggle-joint permitting the blades to approach too closely, as the shoulder can be adjusted to any desired distance. It is new to me that a fœtus can be delivered without traction. If a wedge is all that is wanted, the toggle-joint is a better wedge than the cross-joint. The amount of compression is regulated by the necessities of the case. If the mother is left alone, she compresses the head of her child in her labor. In the cases (eight) where I used this instrument, I could not find a trace of its mark twenty-four hours after delivery. I would never use a handkerchief to tie the handle. I believe that in cases of contracted pelvis where other instruments could not deliver, this could. I had such an experience with a mannikin, in which the outlet was too narrow; failing with the cross handles I delivered with my instrument.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, March 1, 1888.

Thos. M. Drysdale, M. D., in the chair.

Dr. H. A. Kelly exhibited

An Aseptic Two-way Catheter.

A two-way catheter, which will conduct and discharge water and solutions with the utmost freedom, and at the same time allow of perfect and ready cleansing after use, is a great desideratum. In the light of the antiseptic surgery of to-day the use of such two-way catheters as were commonly found in the surgeon's bag a few years ago, is in the highest degree dangerous, owing to the necessarily painfully tedious process of cleansing, and the impossibility of ever being able to assure ourselves that they are clean. One of the best ever devised for the use of the gynæcologist is Bozeman's. This has been modified by Fritsch and Olshausen in such a way that the delivery-pipe and discharge-pipe are two separate pieces, so made that the delivery-pipe enters the larger discharge-pipe, and is held in place by a cap, which is screwed down on it while in use. This will be understood better in examining my modification. The objection to this still held, that although easier to clean than any previous forms, it was still difficult and impossible to assure one's self that it was clean. I have now added my own modification to this instrument, making it now perfect in its utility and answering all antiseptic requirements.

The syringe as constructed by me consists of three parts. First, the delivery-tube, which conducts the stream from the hose connected with the reservoir into the uterus. This tube is well curved, and at its entrance is furnished with a knob to hold the hose better. Its extremity ends in a button, with a series of holes around and a little below the outer margin, in the form of a rose, so placed that the stream is thrown out on all sides and directed a little backwards. The remaining two pieces are the two lateral halves of the *exit* pipe, which is attached very simply by entering each end in the shallow collar under this *rose*, bringing them together around the inlet pipe and screwing the nut down on the thread on their upper end. Each side has a fenestra in it, near the point, and is scooped out near its upper end, so that when the two are fitted together there is a good sized hole here.

When in use water flies with force from the holes at the end, washes with it *débris* and fluid, which enter at once the large fenestræ on the sides, are washed down and out of this large hole into the receptacle. When out of use the cap is unscrewed, the halves fall apart, and every part which has come in contact with infection is at once exposed and readily cleaned. The interior ought to be as highly polished as the exterior. Mr. Gemrig, of this city, has made these instruments for me in a very satisfactory manner. He has made one of solid silver for Dr. Sweetnam, of Canada, which I exhibit here with that I am now using, as well as the older form. If the nomenclature is to be kept up as in the past, it is the *Bozeman-Fritsch-Olshausen-Kelly* catheter.

Dr. Kelly also exhibited a

Cotton Packer.

This instrument has been many months on the shelf by my examining table, and is one of the few I am constantly using. I have showed it to a number of my friends, and at the meeting of the Alumni of the Woman's Hospital in New York, this winter.

Its use is simply to pick up a loose wad of cotton, placed near the vaginal outlet, and with the vagina properly exposed and the uterus redressed, to carry it up into place in the fornices, and pack in one wad after another with perfect exactitude and any degree of firmness required.

It is made of a delicately tapering needle, which balances nicely in the hand, terminating in three diverging tips, a little flattened on the upper and under surfaces.

Dr. B. C. Hirst exhibited

The Placenta from a Case of Unioval Twins.

It was very large in extent; having about twice the ordinary dimensions of a placenta. It formed one mass, with the most intimate anastomosis between the two sets of fœtal vessels. There was in this case hydramnion of one fœtal sac.

Dr. Hirst also showed

A Parietal Bone Presenting a Spoon-shaped Depression.

It had been taken from an infant which died about two days after birth. The labor had been a difficult one, terminated by the forceps; the child had presented by the vertex in R. O. P. position; the pelvis was slightly flattened, head large, O. F. circumference 36½ cm. At the corresponding point internally there was a deep broad depression of the brain substance. The child apparently died from congestion of and serous effusion into the brain.

Dr. Wm. Goodell remarked that Ambrose Paré had compared these depressions to the indentation on kettle-drums. The indentation in this case was very typical. After turning in the flat and narrow pelvis, these indentations were very marked. They occupied then the temporal region and not the parietal, the shorter bitemporal diameter being the one implicated. Hence in turning two mechanical advantages resulted, the small end of the cephalic wedge offered at the conjugate and also a cephalic diameter shorter than the biparietal.

Dr. John C. DaCosta wished to know if Dr. Goodell thought turning could always be done in these cases.

He spoke of a case which had occurred in his practice when the bone was much more depressed than in the specimen shown. The whole left side of the head was bulged in by a large fibroid of the uterus which fitted into the depression like a mortise and tenon joint. The pelvis was of good shape and roomy, os uteri wide open and soft, and yet the head which was at or above the superior strait, in L. O. A. position, would not descend on account of the tumor. As the woman was in good condition and nothing seemed to be going wrong he let her alone for a time. After a little while, by the aid of some manipulation the head began to unlock from the tumor and rotated from O. A. to O. P. position and the child was delivered alive. This case could not have been turned (as membranes had ruptured and uterus gripped the child's body itself) and even if it could have been, there would probably have been a dead baby from pressure on the cord during the long delay that would ensue in delivering the head, as the tumor would most likely have locked under the baby's chin. The forceps could not be put on, on account of obstruction to the left side by the tumor.

Dr. Goodell thought that Dr. DaCosta would have had less trouble if he could have turned the child. He did not think the neck would have been caught. He had been speaking before of the mechanical advantages only and not of the difficulties in the performance of version.

Dr. Longaker presented the following for Dr. Holmes:

The case of Mrs. B., 50 years old, married at 15 years, nulliparous, menstruation always scant and painful, is remarkable on account of series of reflex symptoms, of death from exhaustion and from pain, without organic disease other than ovarian, and of simplicity of operation needed as revealed by autopsy. Mrs. B. consulted me April, 1886, having been treated elsewhere for muscular rheumatism. Pains were of lancinating character along left sciatic, shooting down to ankle. Examination showed ovarian tumor, probably cystic. Prof. Goodell confirmed diagnosis and advised operation, which patient then and subsequently refused. The chief complaint was at first the pain posteriorly along left leg and thigh, which finally also involved similar relations on the right side. In the course of a few months, a persistent tremor attacked both lower extremeties, at first alleviated by manual pressure, subsequently not, and later still extended to arms and hands, and later yet to muscles of face and lips, giving much the appearance of violent chorea, interfering markedly with clear enunciation. During the latter part of life there was oft repeated and painful micturition, with bloody urine, with violent pains starting in lumbar region and shooting along into the bladder and urethra, raising a strong suspicion of renal calculus. This with the other lancinating pains, the tremors and nervous exhaustion consequent upon the many months illness, caused great suffering, the patient often wring-

ing her hands and grasping her hair in agony. Hypodermics of morphine, one-quarter to one-half grain, gave markedly greater relief than same doses by mouth or rectum, even frequently repeated. The apparent increase of tumor was very slow. Autopsy indicated only slight omental adhesions; kidneys healthy. The bladder, uterus, and the two attached cysts, were removed a few hours after death. The dermoid cyst has a long, slender pedicle, attached to the left cornus uteri. It was situated on the right side of the spinal column, opposite the third and fourth lumbar vertebræ, covered by loops of small intestine and by omentum, to which latter it was slightly adherent. It was at first supposed to be a floating kidney, which had undergone conversion into a cyst. Its size, shape, and location, were suggestive of such an origin. The cyst contained chocolate colored sebaceous matter. No hair or teeth. The wall contained calcareous plates. The right ovary is the seat of a multilocular cyst, the size of an average full term fœtal head. The corpus uteri is undeveloped, the cervix constituting the larger portion of the organ. Evidences of chronic cystitis were present.

Dr. M. Price said that this question was coming up daily; cases of pelvic disease were being constantly treated by the general practitioner for malaria, rheumatism, neuralgia, and other kindred diseases, without making any investigation into the actual condition of the patient. In fact, malaria is becoming extremely fashionable, when there is no apparent reason for the condition. He was then treating a case of ovarian disease in a lady now 47 years old, who was married at 15 years, contracted gonorrhœa from her husband at that time, has ever since remained sterile, with scant menstrual discharge, and great pain from the approaches of her husband the pain sometimes being agonizing. She suffers at times from severe pain running down the left leg. Upon examination the ovary was found to be as large as an orange, excessively tender, and when pressure was made in bimanual examination the patient went into convulsions on the table. He did not know what relation this condition may have had in connection to the trouble in her early married life; but of this he was sure, that it was the cause of her barren condition.

Dr. Longaker also exhibited

The Post-mortem Specimens from a case of Carcinoma Uteri.

The following brief notes of this case are presented for Dr. J. S. Gibbs. L. A., married, 39 years old. Always enjoyed good health until five years ago, when her last child was born, since that time she had suffered much from pelvic pains. Menstruation had been excessive. Patient first seen in June, 1887, when a diagnosis of carcinoma of the cervix was made. The disease had invaded the vaginal walls, and the pelvic cellular tissue. From this date I saw no more of the case until Feb. 6, 1888. She had been free from pain, but hemorrhage persisted. Vaginal examination revealed advance of the disease. It provoked such a profuse hemorrhage that application of Monsell's solution was required to arrest it. When the hemorrhage was under control, pledgets of cotton saturated with terebene and olive oil (1–4) were packed against the cervix according to the plan of Betrin, of Geneva. This medication diminished the offensive odor, but I strongly suspect it had something to do with the rather untimely demise of the patient. In a few hours from the time of the application she sank into a somnolent state from which it was difficult to arouse her, with almost complete suppression of urine and strangury, and death in 36 hours.

A peculiarity of the case was absence of cachexia and emaciation.

Autopsy.—The cervix was extensively infiltrated and ulcerated. The corpus shows a few nodules. The ureters are dilated as are also the pelves of the kidneys.

Dr. G. E. Shoemaker thought that the statement that death was probably due to an application of terebene should be carefully considered. He was constantly using, and observing the use of the drug internally in much larger quantities than could be absorbed from such an application, without a sign of irritation. Might not the death from uræmia have occurred independent of its use?

Dr. Longaker believed that the application terebene did hasten death. The strangury and suppression came on quickly after it had been used. The case lacked some of the ordinary symtoms of uræmia.

Dr. Wm. Goodell exhibited a

Specimen of Conjoined Twins,

which had been presented to him by Dr. Junius F. Fuller, of Roxborough, N. C. The specimen was a perfect one—the bodies were united at the hips and there were three feet in common. Some years ago an analogous living specimen of conjoined twins was on exhibition in this city, and he had brought them before his class at the University, and had given a lecture upon the subject. From investigations then made he found that this form of conjoined twins was not a very rare one,

as Aldrovanus and other old writers had described and figured them. The specimen which he presented must have been aborted at the third month of utero-gestation.

Dr. Goodell also presented a

Specimen of hydro-salpinx.

It was the largest specimen he had ever seen; although he had met with much larger specimens of pyo-salpinx. The case had been treated by many gynæcologists and the true condition had not been recognized. There had followed the operation a complete relief from pelvic pains, but menstruation had continued up to the present time. The periods were, however, becoming less frequent. Since it was contended by some eminent surgeons, that when menstruation continued after the removal of the uterine appendages, some of the ovarian stroma must have been left behind, he wished to call the attention of the Society to the complete extirpation in this case of both ovaries and tubes. Although the former were more or less adherent, it was evident from the specimens that not a particle of ovarian stroma was left behind.

Dr. M. Price said he had seen two cases in his practice where the menstrual discharge did not cease after the removal of the appendages. In one case it lasted for a year and a half, in the other six months. He had no doubt but Dr. Goodell's case would show the same result. There was but little doubt in the mind of most operators that the removal had not been complete.

Dr. W. H. H. Githens, who resigned the Secretaryship of the Philadelphia Obstetrical Society the first of the year, after an uninterrupted service of eleven years, was presented this evening, in the name of the Society, with a very handsome mantel set (including clock and side ornaments) in recognition of the very valuable services he had rendered the Society during his long term in office.

Officers of the Philadelphia Obstetrical Society for the ensuing year: *President*, Thos. M. Drysdale, M.D.; *Vice-Presidents*, Chas. H. Thomas, M.D., J. C. DaCosta, M.D.; *Secretary*, J. M. Baldy, M.D.; *Treasurer*, Alfred Whelen, M.D.; *Curator*, T. Hewson Bradford, M.D.

The *Allgemeine med. Central-Zeitung* says that Prof. Ball obtains successful results in acute vaginitis from suppositories of oil of copaiba and cocoa butter, each one drachm; and opium one-half grain. These may be allowed to stay in the vagina for twelve hours.

Periscope.

Antifebrin in Feverish Conditions in Childhood.

This paper, by J. Wedervitz (*Wiener med. Wochenschr.*, Nos. 17, 18, 1887), records fifty-three cases, including scarlatina, measles, simple and with pneumonia, erysipelas, croupous pneumonia, etc., which were treated with antifebrin. Two noticeable points, not previously observed, were brought out.

First, that the effect of the drug was seen within from ten to twenty minutes after it was taken, and the fall of temperature was very rapid till it reached its lowest point, when it began slowly to rise again, the rapidity of the fall depending more on the individual and the disease than on the dose given. The second point was the surprisingly favorable influence of the antifebrin on the general condition of the children. In almost every case restlessness was overcome, and sleep followed within a quarter of an hour after the dose was taken. Of the various diseases under treatment scarlet fever and erysipelas were the least affected by the drug; measles and pneumonia responded more certainly, and tubercular affections complicated with measles most quickly of all. The pulse was not affected to the same extent as the temperature. The dose given was about two grains to children three or four years old, and four to five grains to older children. The smaller doses, as a rule, were sufficient in the badly nourished, who as a rule react more energetically to the drug. As much as 30 grains was occasionally administered daily. Antifebrin had no noteworthy effect on the general course of the disease.—*Edinburgh Med. Journal*, December, 1887.

Uses of Cannabis Indica.

In *The Practitioner* of February, 1888, Surgeon-Major J. F. P. McConnell, of the Bengal Service, in an article on this subject, calls attention to some uses of cannabis indica which do not seem to be as well-known as they deserve to be. The contradictory results obtained by different men he thinks is entirely attributable to the difficulty in obtaining fresh preparations of the plant; for the resin—the so-called *Cannabin*—upon which the properties of the Indian hemp depend, certainly deteriorates by keeping or storage. When care is taken in this respect the therapeutic value of the drug in certain affections of the nervous system—tetanus, neuralgia, migraine, etc.—and its powerful

effect in controlling uterine hemorrhage, has been repeatedly recorded by competent observers, and its employment for the relief of such affections is well understood and frequently resorted to. In the present paper, however, he speaks especially of three conditions. One of these conditions is *anorexia*—loss of appetite consequent upon exhausting diseases, such as prolonged fevers, diarrhœa, dysentery, phthisis, etc. There is a repugnance to and intolerance of food in almost every form, which do not always yield to acids, bitters, and nux vomica as usually given. In such cases cannabis in small doses (♏ v–x of the tincture, or gr. ¼–½ of the extract) have been found very useful. The tincture may be given in emulsion, with a small quantity of mucilage and simple syrup, and flavored with rose-water. The extract may be given in lozenge or bonbon form, after being rubbed up with white sugar, gum acacia, etc., to proper consistency. The mixture or lozenge may be given three times a day, half an hour before meals, and will frequently in two or three days bring back appetite for food and promote its digestion. Both these preparations are very palatable and readily taken by even fastidious patients.

A second condition is *dyspeptic diarrhœa*, and the diarrhœa that is associated with defective action of the liver and deficient secretion of bile, which tends to diarrhœa alba (tropical diarrhœa), in which there is a tendency to action of the bowels soon after meals, and a consequent hurrying of imperfectly digested food through the bowels, accompanied with active vermicular movements of the latter, with much flatulency, borborygmi, etc. In the earlier stages of this disease cannabis is often of great service in controlling the diarrhœa. Even in more advanced stages of tropical diarrhœa cannabis is sometimes useful. The disease seems to be one primarily and essentially of the liver, and cholagogue remedies must be used. Of these mercury is most reliable—as blue pill or gray powder. The mercury is given at night, and the cannabis during the day. He begins with ♏ x of the tincture, and gradually increases the dose to ♏ xv, xx, or xxx, three times a day or oftener. A suitable combination is:

Tincture of cannabis indica	♏ x–xx
Subnitrate of bismuth	gr. x
Mucilage of acacia	ʒss
Comp. spirit. of chloroform	♏ xx
Cinnamon or peppermint water	fʒj

Give before or after food, preferably after, especially when the dose is increased, since in this way unpleasant symptoms, such as headache, giddiness, hallucinations, etc., are obviated. Both in tropical and in dyspeptic diarrhœa cannabis is better than opium, because it in no way interferes with the bile-forming function of the liver. But when tropical diarrhœa has gone so far that the functional disorder of the liver is succeeded by organic changes, cannabis is useless.

A third condition in which cannabis is useful is in cases of chronic cardiac disease, and in chronic Bright's disease as a *hypnotic*. In cases of distressing insomnia and general inquietude, with an enfeebled heart, in which chloral seems inadmissible, the administration at bedtime of ♏ xv–xx of tincture of cannabis, with a small dose of chloral (gr. x) and ʒss of bromide, will often give the desired effect. He has assured himself by check experiments that this good hypnotic effect is not to be attributed to the chloral and bromide, but to the cannabis indica.

Rare Case of Lead Poisoning.

At a meeting of the Medico-Chirurgical Society of Edinburgh, November 2, 1887, Dr. Byrom Bramwell showed a man suffering from peculiar symptoms, the result of lead-poisoning. The patient had presented himself at the Infirmary a fortnight before, complaining of dimness of vision, severe headache, and tremor affecting especially the right hand, but distributed generally over the body. The acuteness of vision was found on examination to be reduced to less than one-tenth, and the fields very much restricted. Greens and blues could not be distinguished, and the color fields were much reduced. There was no optic neuritis. The fundus was, in fact, perfectly normal—a very interesting, and, so far as Dr. Bramwell knew, a very rare condition in cases of lead blindness. Under large doses of iodide of potash, and sulphate of magnesia purgatives, the headache had disappeared, and vision was now normal.—*Edinburgh Medical Journal*, Feb., 1888.

Treatment of Articular Rheumatism.

Aufrecht (*Deutsche med. Wochenschrift*, January 12, 1888) has had an interesting experience in the treatment of rheumatism. As the result of extensive trials he came to use salicylic acid in acute cases to the exclusion of all other remedies, and with complete success so far as the disease was concerned. He used the acid in full doses, ninety grains a day for the first two or three days, and

sixty to forty-five grains during the following eight or ten days. Unfortunately, this treatment could not be fully carried out in every case. Burning pain in the stomach, vomiting, tinnitus aurium, or dyspnœa, sometimes made the drug unbearable. The use of salicylate of soda in corresponding doses was no improvement. Not only did it cause the same disagreeable symptoms as the acid, but in Aufrecht's hands was not as effective in subduing pain and fever. On the introduction of salol, a trial of it showed a marked improvement in many respects. Causing but little local or general disturbance, its use could be continued almost indefinitely. Thus, one patient took altogether more than 3,500 grains in doses of ninety grains daily. On the other hand, in acute polyarthritic cases, it was not so effective as salicylic acid. Whereas the latter usually subdues pain and fever in the first twenty-four hours, salol requires three or four days, though pain was greatly ameliorated within the shorter period. In consequence of its many advantages salol was adopted as the routine treatment by Aufrecht, but on the occurrence of a fatal case of acute endocarditis under its use—a thing not met with among six hundred cases treated with salicylic acid—it was discontinued. Since then what might be called the mixed treatment has been followed. In this, acute cases receive during each of the first two days ninety grains of the acid, and after that the same amount of salol. Later, the patient still remaining in bed, the salol is reduced to sixty grains daily. As salicylic acid is usually well borne for two days, but frequently no longer, this recommends itself as the best routine treatment. If possible, the acid may be continued; if, on the otherhand, it cannot be taken, salol may be used. In chronic articular rheumatism salol is preferable in every respect, not only avoiding the dangers attending prolonged use of salicylic acid, but offering more positive assurance of cure.—*American Journal of the Medical Sciences*, March, 1888.

Creasote in Phthisis.

According to the *Lancet*, January 28, 1888, Dr. V. T. Bushuyeff has recently reported in *Vrach* the results obtained by treating cases of phthisis with creasote in Prof. Koshlakoff's clinic in St. Petersburg. The quantity of creasote given was usually about three drops during the twenty-four hours. The number of cases so treated was 20, and the duration of treatment from one to six months. Of these 20 cases, 10 were in the first stage, 6 in the second, and 4 in the third. In all the cases in the first stage the treatment was followed by a marked improvement. Four out of the 6 in the second stage were benefitted, but none of those in the third stage. In five of the cases in the first stage it may almost be said that the creasote produced a cure, because the dulness and bronchial respiration, as well as the râles, ceased. In only one patient did the creasote produce any undesirable effects, and this patient, who was in the last stage of the disease, took six drops (instead of three), for three days. The result was acute nephritis with anasarca. The drug may be given in wine, glycerine, cod-liver oil, and in capsules or pills.

Dislocation of the Head of the Femur on to the Pubes.

At the meeting of the Sheffield Medico-Chirurgical Society December 8, 1887, Mr. Pye-Smith (*Lancet*, January 14, 1888) reported the case of a man, 56 years old, who became overbalanced in walking round a low wall in the dark, and fell backwards, dislocating the left hip. He was brought to the Sheffield Public Hospital and Dispensary late the next day. The injured limb lay straight by the side of its fellow, but the foot and knee were everted almost to a right angle. The head of the femur was easily seen and felt beneath Poupart's ligament, just external to the femoral artery, which was slightly displaced inwards. The two thighs measured precisely the same from the anterior superior spine of the ilium to the adductor tubercle of the femur, but the right leg was an inch shorter than the left owing to an old fracture above the ankle. Bryant's line was also equal on the two sides, but the great trochanter was a quarter of an inch nearer the middle line of the body on the injured side than the sound side. Reduction was effected twenty-two hours after the accident by traction in the axis of the limb in a slightly over-extended position, combined with rotation inwards.

An herpetiform Affection of the Tongue.

Fournier reports to *La Semaine Médicale* upon an affection of the tongue which appears, not rarely, several years after an attack of syphilis which has been seemingly well cured. It appears in erosions, especially on the margins of the tongue, which are marked by great resistance to anti-syphilitic treatment, as well as by great capacity to repeat themselves after cauterization, and similar methods of treatment. He identifies these lesions with those of "relapsing herpes of the genitals" of Doyon—a very obstinate form of herpes of the genitalia, occurring

after syphilis. His opinion is based upon the following facts: 1. The affection appears only in the form of quite superficial erosions, affecting the mucous membrane. 2. The erosions are small, averaging from the size of a lentil to that of a grain of wheat, but sometimes scarcely the size of a pin. 3. The erosions are numerous and scattered; they are found with especial frequency on the margins of the tongue, but are also present on the back of the tongue. 4. They are ephemeral, like herpes; if let alone they last about eight to fourteen days, provided that no specially unfavorable influence is at work, such as tobacco smoking, or bad condition of the mucous membrane of the mouth. 5. The extraordinary propensity to relapse is in favor of herpes, especially the relapsing form of the latter disease. 6. Finally, the herpetic character of the polycyclic configuration of the erosions is pronounced.

Herpes presents itself ordinarily as a group of blisters, which grow peripherally, and coalescing burst, leaving behind an eroded surface, which also exhibits the polycyclic form. Only one affection shows a similar configuration of superficial lesions, namely, the vulvar, perivulvar and perianal syphilide; but in this latter the circles are single, and the indentations considerably larger. As regards the color of these erosions of the tongue, they seem somewhat red, and before the epithelium is stripped off, more grayish. They cannot be taken for blisters, on account of their ephemeral character. The author believes their return is brought about by the immediate use of mercury, tobacco, etc. For this reason a mercurial treatment aggravates the disease. He regards the affection as non-syphilitic. — *Deutsche Medizinal-Zeitung*, Dec. 15, 1887.

Catarrh of the Antrum.

In cases of catarrh of the antrum, Dr. Schiffers, of Liège, instead of extracting the second molar, gains access to the cavity through the opening in the middle meatus of the nose. Through this he inserts a director, and with the help of a curved, probe-pointed bistoury, he opens up a passage for the free exit of the confined secretion. By the use of cocaine, the patient suffers but little during the operation. Dr. Schiffers points out that catarrh of the antrum is frequently overlooked and mistaken for an affection of the mucous membrane of the nose. When an abundant fetid discharge runs from the nose, especially when it is intermittent, the existence of disease of the antrum should be suspected. A careful search should then be made, with the help of the nasal speculum and a good light, for the welling up of the secretion through the foramen in the middle meatus.—*Lancet*, Dec. 31, 1887.

Vaccination in England.

The *British Medical Journal* in its summary with regard to vaccination for the year 1887, says: No notable event concerning vaccination has been recorded during the year. Arm-to-arm vaccination has been carried on at all the stations except that of the Local Government Board at Lamb's Conduit Street, where the practice is to vaccinate from the calf; here the demands for vaccination have steadily grown, and we learn that the number of applicants is now so great that the Board have to face either a limitation of the usefulness of the institution, or its relief by the opening of a similar station in another part of the metropolis.

With regard to vaccination of children, Dr. Stevens has shown for London that the protection of children is increasing, and that the alleged deaths from small-pox in early life after vaccination become enormously reduced when the true facts are known. Thus, of 116 children under 15 years of age stated to have died of small-pox after vaccination, there were only two on whose history of vaccination he could rely, and of 24 deaths in children under 5 years of age in which the vaccination was entered as doubtful, he found that 11 had not been vaccinated at all, and 6 had been vaccinated during the period of incubation of small-pox, and therefore too late to be protected.

Tamponing the Uterus with Iodoform Gauze.

Two papers have recently been presented on this subject. One is by Dr. A. Dührssen, of Berlin (*Centralblatt für Gynäkologie*, No. 35, 1887); the other by Dr. F. Fraipont, of Liège (*Les annales de la société méd.-chirurg. de Liège*). Both these authors recommend the tamponing of the uterus with iodoform gauze in atony of the uterus after premature birth and birth at full time, in case the ordinary hemostatics—injections of ergotin, manipulation of the uterus and hot douches—do not accomplish the desired object. It is asserted that these tampons are at the same time disinfectant. The strips of gauze may be removed after twenty-four hours, but may even remain two to three days without a sign of decomposition in the cavity of the uterus occurring.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks ana postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

CHEERFULNESS AS AN AID TO MEDICINE.

There are few characteristics which go further toward making a successful physician than a judicious cheerfulness, which, while it does not underrate the importance of human ills, does not overrate them either. The bright, sunny disposition of certain medical men does as much good as their medicines. This is the doctor's contribution toward the cure or alleviation of disease. But there is something of the same sort which may be contributed by the patient, and his friends. Both he and they may do much to supplement the labors of the physician by maintaining as much as possible a cheerful frame of mind. We have all heard, indeed, of patients so hopeful that they insisted they would get well, when the doctor said they would die—and did it, too. Of course no physician could approve of such insubordination; but we are all willing to have our patients help us by making a good, brave, cheerful fight for recovery as long as there is a fighting chance. Unfortunately there are times when low spirits or bad judgment put great obstacles in the way of a patient's recovery. An illustration of this is recorded in the *Monthly Bulletin of the Iowa State Board of Health* for January, 1888. In the case referred to, a woman with consumption, who was a mother, sat for much of her time in a room on the walls of which hung two mottoes: "What is home without a mother?" and "There is sweet rest in heaven." The editor of the *Bulletin* very properly suggests, that the frame of mind produced by contemplating these mottoes—however excellent they may be in themselves—could hardly fail to be prejudicial to the case of the mother in question.

No right-minded medical man would seek to restrain the tender sentiments of his patients, or to interfere with the comforts of a religious hope; but no more can any sensible medical man doubt that both of these, indulged in an unwise way and dwelt upon at unfit times, may do much harm. For this reason medical men may well look to the surroundings of their patients' minds as well as to those of their bodies, and do all that they can to prevent the mischief which may be caused by gloomy reflections, or morbid longings. It is no small part of his office to remove such influences judiciously and considerately; as it is no small part of the duty of his patient to consent to their removal, and to cultivate a hopeful and cheerful frame of mind. This is the only wise and right way; and it is as justifiable from the standpoint of the moralist as from that of the physician.

THE PRAISE OF COUNTRY PHYSICANS.

Medical men who reside in the cities, and are surrounded with all the conveniences which are found there, have often only imperfect ideas of the hardships which are borne by physicians who practice in the country. To such persons we would heartily commend an effort to learn what their country brethren go though in their labor of humanity, in order that they may appreciate as they should the work which the latter do. If this were fully understood the city physican would think more highly of his brother of the country, and would probably feel that

the brilliant achievements of the great medical centres by no means eclipse the worthy services and noble sacrifices of the country districts. For downright heroic work no men in the medical profession can compare with those who press over dangerous roads or through swollen and icy streams, by day and night, in their errands of mercy to the sick and injured.

These reflections are prompted by reading in the Williamsport *Weekly Sun and Banner*, Feb. 23, 1888, a sketch of the experiences of Dr. Thomas Lyon, who for more than fifty years has practiced medicine in and about Williamsport, Pa., and who still lives to enjoy the esteem which such a long career of usefulness must bring. The narrative of this career is so interesting that we wish we had space in which to place it all before our readers. It would, we are sure, excite a warm glow of sympathy in many a heart, and a feeling of admiration in others whose experiences have been too easy to permit them to fully sympathize with it. But to all alike, we think, the thought would come that our country may well be proud of a set of men to whom such experiences, such sacrifices, such achievements are no rare things; and it would encourage anew the thousands of faithful, earnest men all over our land who fill the important and honorable post of country physicians.

TREATMENT OF INFANTILE DIARRHŒA.

Sometime ago, HAYEM, of Paris, announced that he had obtained excellent results in the treatment of the diarrhœa of little children, characterized by the passage of green stools, with a solution of lactic acid. At the meeting of the Société Médicale des Hôpitaux, on January 13, he reported the result of further experimentation with this simple remedy, and his increased confidence in it. His former announcement is modified, in that he advocates the use of larger doses *per diem*. He now uses a two per cent. solution in water, sweetened with cane sugar, and gives of this from twelve to twenty coffee-spoonfuls a day; that is about a half-teaspoonful at a dose, every half hour, except at nursing times. One of the good effects of this remedy is that it puts a stop to the vomiting, which is often so obstinate in these cases.

Hayem has used lactic acid, also, in some cases of chronic diarrhœa in adults. In the greater number of cases of entero-colitis, or of chronic intestinal irritation due to an improper regimen, and accompanied by gastric dyspepsia, the administration of lactic acid has brought about a rapid cure. To adults, Hayem gives three tablespoonfuls of a two per cent. solution daily.

At the same meeting M. Sevestre confirmed the opinions of Hayem. He, however, gives more of the remedy, administering a coffee-spoonful every five or ten minutes in severe cases. In some cases of bilious diarrhœa which resist this method, Sevestre has had good results from the use of large doses of bicarbonate of soda, namely about ten grains for each pound of the weight of the child.

These facts encourage the belief that lactic acid is a valuable addition to the number of remedies applicable to the treatment of the diarrhœa of infants and little children. In considering the treatment of the diarrhœa of of infants, however, it is well to bear in mind a point to which ESCHERICH, of Munich, has recently called attention (*Jahrbuch f. Kinderheilkunde*, 1887), namely, that the persistence of diarrhœa is often dependent upon persistence in the use of improper food. And it appears that certain forms of diarrhœa are dependent upon decomposition of certain kinds of food. In a mixture of albuminous food with hydrocarbons, the latter appear to undergo decomposition first. An example of this is seen in milk, in which the acid fermentation precedes the decomposition of the albuminoids. For this reason it seems rational to use albumen-water in cases of diarrhœa dependent upon decomposition in the upper part of the intestinal tract, and accompanied by acid stools. On the other hand, a diarrhœa marked by fetor, and the signs of decomposition of the albuminoids, with alkaline stools, requires a withdrawal of the latter from the food and the use of hydro-

carbons alone; and such a course often leads to rapid recovery.

This view of the causation of infantile enteritis has a very important bearing upon the use of the remedies mentioned above, namely, lactic acid and bicarbonate of soda, and may aid very decidedly in determining the choice between them. More than this, a proper recognition of the significance of acid or alkaline stools may obviate the necessity for using either of these remedies, if it leads to a correction of the diet, and thus to recovery.

THE REPORTER AND "READING NOTICES."

Ever since the MEDICAL AND SURGICAL REPORTER passed from under the control of its former editor, it has pursued the policy of rigidly excluding from its columns of reading matter the puffs of advertisers, which are known as "reading notices." These are much desired by advertisers, and we believe advertising contracts are often made under an expressed or implied promise that "reading notices" shall be given in addition to the space regularly paid for. Observant readers of medical journals must have remarked that there are but few which keep their advertisers strictly to the advertising pages. The few that do this sometimes lose tempting opportunities to make money; and it cannot but be painful for them if they both lose the money and miss the reputation which they are trying to secure. This is the case in which we now find ourselves; for we see in the columns of some of our contemporaries, notices of wares credited to the MEDICAL AND SURGICAL REPORTER, which we have no knowledge of, and which could not be published now in the reading pages of this journal for any price. So we beg our readers to take notice of the rule we have adopted, and to which we have adhered—that no "reading notices" are ever published in the REPORTER; and we ask our contemporaries to do us the favor of refusing to admit to their columns what might place this journal in a false light. We will do all we can to aid our fellow editors in getting rid of the nuisance of so-called "reading notices," and if they join us, the time may come when no medical journal need tremble, no matter what pressure is brought to bear on it, by those who have no special interest in the tone of medical journalism.

THE AFTER TREATMENT OF TRACHEOTOMY.

In the *Deutsche med. Wochenschrift*, February 16, 1888, DR. KARL ROSER, of Marburg, refers to the statistics collected by Drs. Lovett and Munro, and published in the *American Journal of the Medical Sciences*, July, 1887, in which the death ratio was shown to be seventy-two per cent. in a total of 21,853 operations of tracheotomy. This mortality is much higher than that which has prevailed in the hospital at Marburg during the last three years and a half, in which forty-seven such operations were performed with only forty-seven per cent. of deaths. This satisfactory result Roser attributes to the use of a modification of the ordinary tracheotomy canula, which he devised. This modification consists simply in wrapping round the canula a strip of gauze moistened in a sublimate solution, about two-thirds of an inch wide and three inches long, and rubbing powdered iodoform into it while yet moist. When it dries the gauze forms a smooth hard envelope surrounding the canula, and extending from near its extremity to the guard. When the tube, thus covered with iodoform gauze, is inserted into the trachea, it absorbs moisture, becomes soft, and completely fills the lumen. The result is to prevent the descent of irritating or infectious materials from above the canula, and to render aseptic the portion of the trachea with which it is in contact.

The custom at Marburg is to leave the first canula in place for at least two days, and then to substitute for it another, prepared in a like manner. After five days it is believed that there is no longer danger of secondary infection of the trachea, and no specially prepared canula is needed; in fact no canula is needed if the larynx is clear. Roser believes that this method of modifying the ordinary tracheotomy tube is of service even when the trachea is already implicated in a diphtheritic process.

The advantages already mentioned are not all that are claimed by Roser for what he calls the "iodoform tampon canula;" but they seem to justify his favorable opinion of it, and they may partly account for the good results which have followed the operation of tracheotomy at Marburg. It certainly seems worth while for American surgeons to know what it seems to have accomplished, and to take into consideration the propriety of testing its merits for themselves.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

PHYSICAL CULTURE FOR HOME AND SCHOOL, SCIENTIFIC AND PRACTICAL. By Prof. D. L. Dowd, of the Home School for Physical Culture of New York. With 80 illustrations. Small 8vo, pp. xxii, 300. New York: Fowler & Wells Co., 1887. Price, $1.50.

This book is one of the most interesting works on physical culture which we have ever seen. The author is a man who, by the methods he describes, has developed his frame from that of a narrow-chested, almost consumptive-looking individual to that of an athlete. But he does not regard the mere cultivation of muscular strength as the proper end of physical exercise. He takes the sensible and correct view that the object of judicious exercise must be to develop the whole of the body symmetrically, and to improve its tone rather than its bulk. The method he recommends is founded upon accurate anatomical knowledge, and brings into action all the muscles, sometimes singly and sometimes in groups.

As a book of instruction this work leaves little to be desired, and one of its greatest merits depends upon the fact that it calls for but little apparatus, and for none which is not within the reach of everybody. We can recommend it heartily to our readers, especially as we believe that its advice to persons afflicted with moderate deformities of the legs or spine is sound and worthy of acceptance. To schoolteachers, without the aid of a trained educator in physical development, the book will prove of especial value.

A MANUAL OF PHYSIOLOGY. A Text-Book for Students of Medicine. By Gerald F. Yeo, M.D., Dubl., F.R.C.S., formerly Professor of Physiology in King's College, London, etc. Third American from the second English edition. 8vo, pp. 758. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $3 00.

This is a book whose modest title hardly does justice to its contents. It is indeed a manual, and no doubt one of great value for students of medicine. But in addition to this it is so thorough, though condensed, that it must prove of great service to any practitioner. It lacks some of the details which are usually included nowadays in more pretentious treatises on physiology; but what it does discuss is discussed so clearly, so succinctly, and so soundly that it is peculiarly adapted to the needs of busy men. It contains three hundred and twenty-one illustrations, which worthily supplement the text, and is handsomely printed and bound. We can heartily recommend it to our readers as the best succinct work on physiology with which we are acquainted.

DISEASES OF THE HEART AND CIRCULATION IN INFANCY AND ADOLESCENCE. By John M. Keating, M.D., Obstetrician to the Philadelphia Hospital, and Lecturer on Diseases of Women and Children, etc., and William A. Edwards, M.D., Instructor in Clinical Medicine and Physician to the Medical Dispensary in the University of Pennsylvania, etc. Large 8vo, pp. 215. Philadelphia: P. Blakiston, Son & Co., 1888.

This work has been published in monthly instalments in the *Archives of Pediatrics*, during the year 1887, and is now presented to the medical profession in the more convenient shape of a book. It is a very handsome volume, illustrated with wood-cuts and two photographs. It contains an admirable summary of the literature of its subject, supplemented by the facts and opinions gathered from the observations of the authors. It discusses fully the phenomena of the diseases of the heart and disturbances of the circulation in regard to their nature, mechanism, causation, natural history and treatment. We do not know of any book in which these matters are so fully discussed, especially as they concern infants and children, and Dr. Keating and Edwards have done the profession good service in presenting them in such a clear and practical way.

THE THREE ETHICAL CODES. 7½ x 4½ inches, pp. 55. Detroit, Mich.: The Illustrated Journal Co. Price, 50 cents.

This little book contains the Code of Ethics and the Constitution and By-Laws of the American Medical Association, the Code of Ethics of the American Institute of Homœopathy, and the Code of Ethics of the National Eclectic Medical Society. Of the three Codes, that of the American Medical Association is the longest, and that of the Eclectic Society is the shortest, while much of the Homœopathic is similar to that of the first named. It is a handy little book for reference, as occasion may require.

Pamphlet Notices.

Four Months Among the Surgeons of Europe. By N. Senn, M.D., Ph. D., Milwaukee, Wis. From the *Journal of the American Medical Association*. 162 pp.

The Nature of Contagion. By J. W. McLaughlin, M.D., Austin, Texas. From *Daniel's Texas Medical Journal*. 8 pp.

Agnosticism, Based on Physical Science. Second (revised) edition. By Alex. W. Stein, M.D., New York. 1888. 20 pp.

Elixir Paraldehyde: The Coming Remedy, as a Substitute for Opiates and Anodynes. By A. B. Cook, A.M., M.D., Louisville, Ky. From *Progress*, January, 1888. 4 pp.

—Dr. Senn's little book contains a series of letters written by him to Dr. Chr. Fenger, of Chicago, and published last year in the *Journal of the American Medical Association*. They are extremely interesting as giving the impressions made upon a careful observer by the medical men and medical institutions

of Europe. Everywhere Dr. Senn went he was received courteously, and enjoyed the hospitality which an intelligent American is sure to receive. Those who have had the pleasure of experiencing this hospitality cannot fail to enjoy Dr. Senn's description of his experiences; and those who have not had this pleasure may learn much that is interesting and gratifying from what he relates, and can make a sort of acquaintance with men of well-known names, whose writings they are already familiar with.

—Dr. McLaughlin's pamphlet contains the substance of his remarks upon two papers read at a recent meeting of the Austin District Medical Society, one on Septic Fever and the other on Typhoid Fever. It describes in an intelligent way the modern theory of contagion, which holds that this is due to specific micro-organisms and their products.

—The title of Dr. Stein's pamphlet is misleading; for his address contains an argument which, starting with a description of the limitations of human knowledge, leads up to an expression of faith in immortality as expressed in the language of Socrates and of St. Paul. One who holds to a religious faith may shrink a little at the first part of this pamphlet; but he will certainly be comforted when he finds how clearly Dr. Stein makes the distinction, too seldom made, between confessing ignorance, and denying. Man may not know he is immortal; but no more does he know anything positively of the material and phenomena of this life; and it is no violent straining of logic to assert that if matter, of which we know so little, is indestructible, so may consciousness, of which we know but little, be also indestructible.

—Dr. Cook has a very high opinion of the value of paraldehyde, which is undoubtedly a very useful hypnotic. Its objectionable taste, he says, is well disguised in an elixir which the Louisville druggists prepare. The dose of paraldehyde in this Elixir is from forty-five minims to a fluid drachm and a-half to the ounce, and Dr. Cook has found that excellent results are produced by the use of tablespoonful doses of the compound.

Correspondence.

Antipyrin in Pleuro-pneumonia.

Editor Med. and Surg. Reporter:

Sir:—I send a brief report of a case which I would like to see published in the Reporter.

On February 3, I was called to see Mr. S——, about 34 years old, and found him suffering with pleuro-pneumonia of the left side. This was his third attack, the former ones, occurring four and eight years ago respectively. As he was given to alcoholic excesses, I was a little doubtful of his recovery, especially as the case was a grave one and pointed to speedy dissolution. After the ninth day, there was marked improvement, for which I am indebted—under Divine Providence—to that newly-discovered, wonderful medicine "Antipyrin," which I think, gives promise of great usefulness, especially in cases of this character.

I hope some brother physician will give this drug a trial, and obtain as good results.

Yours truly, Joseph Hopson, M.D.

St. Matthews, Ky.

Feb. 29, 1888.

Advice wanted for Tinnitus Aurium.

Editor Med. and Surg. Reporter:

Sir:—I would be glad to have advice from the readers of the Reporter as to the treatment of the following case:

Mrs. E. C., 49 years old, married, a healthy, robust looking woman, weighing about 160 or 170 pounds, has passed the menopause with little trouble. She is the mother of one child. She applied to me for treatment in July, 1887, complaining of violent periodical tinnitus aurium: noise in both ears, sometimes musical, at others roaring, whistling, hissing, etc., with fulness and throbbing of head. Sleep relieves her, but is often prevented by the tinnitus, which worries and annoys the patient greatly. She is a woman of active habit, and often tries to "work off" these spells, but is not always successful. She cannot tell when the spells will come on. They frequently last one, two or three days, and then cease. The patient is apparently healthy in every other way; her functions are normal, and she has never had catarrh, while her ears and nose seem to be healthy and normal. After a thorough examination I made the diagnosis of *tinnitus aurium* from hyperæmia of the brain, and gave the patient ergotin in large doses. This produced no relief. Then I advised bleeding; but the patient did not consent until just before leaving here, and as she had to ride home one hundred miles by wagon I refused to perform venesection then, but prescribed bromide of potash in large doses. This seemed to promise permanent relief; but, after six months of such treatment the patient writes as follows; "At first I seemed much better, but the medicine seemed to lose its effect, until finally, within the last three or four weeks, I am as bad off as ever. I am so disheartened and so annoyed with this interminable noise in my head, that it is with difficulty I can settle myself at anything. My head becomes tired and heavy with a dull fulness, until I am almost bewildered. I sleep better than last summer, my bowels have been very regular, my appetite good—too good, for at times I am troubled with dyspepsia. I still cling to the hope that I may find relief; yet I get, oh! so weary of mind and body, with no rest day or night, only when asleep. I get nervous at times and am almost afraid to sleep, fearing I scarce

dare say what—that the poor weary and worn machinery might give out—not in death, but worse." She further adds: "I am well in every other respect but this one." After this I advised the patient to come and be bled, and I prescribed for her bromide of potash in large doses, with tincture of aconite, and a strong purge every few days.

Arizona, W. N. S.
February 15, 1888.

Onanism and Masturbation.

EDITOR MED. AND SURG. REPORTER:

Sir:—There is one subject upon which I would like a little information, and that is, if custom has made the terms "masturbation" and "onanism" interchangeable? They seem to be so regarded, almost all the writers in the medical papers that I see, so use them. The medical dictionary says "masturbation is self-pollution with the hand," and "onanism is masturbation."

I was taught, and still believe, that masturbation is a solitary vice, that may be performed by one individual of either sex, while onanism requires the co-operation of two persons of opposite sexes. Whatever may be the meaning of masturbation, a clear idea of onanism may be found in the book of Genesis, chapter xxxviii, and verse 9, where the name of one of the parties will be found to be the same as that given to the like act of the present day. A. BURT, JR., M.D.

Wakefield, Kansas.
Feb. 28, 1888.

[Our correspondent is right. The term "onanism" is used incorrectly when applied to masturbation. *Onanism* consists in withdrawing the male organ from the vagina before ejaculation takes place. *Masturbation* is provoking the sexual orgasm by unnatural and mechanical means. Originally the word was applied only to such provocation in which the hand was employed. But at present it is used to indicate any unnatural and mechanical process by which the orgasm is excited.—ED. REPORTER.]

—Mr. G. J. Romanes has been elected Fullerian Professor of Physiology at the Royal Insttution, London. He intends to devote the three years of his professorship to one continuous course of lectures on "Before and After Darwin." This year's course—"Before Darwin"—will give an historical survey of the progress of scientific thought and discovery in biology from the earliest times till the publication of "The Origin of Species." Next year's course will be on "The Evidences of Organic Evolution," and the third year's course on "The Factors of Organic Evolution."

NOTES AND COMMENTS.

A Possible Carrier of Contagion.

Dr. D. Lichty, of Rockford, Ill., writes to the *Medical Record*, March 3, 1888, that in an active and extended experience of twelve years in country practice, he has observed that it is the custom among the farmers, especially the younger families or beginners, to make butter in the house in larger or smaller quantities; and in winter-time, to prevent the milk from freezing, it is usually kept in the kitchen, which is also the living-room, and often the only place in the house where a constant fire is kept. In this room the convalescents stay, and to it are often carried the sick, whatever may be the nature of their illness, whether diphtheria, scarlet fever, or what not, because it is probably the only room where an attempt at equable temperature would be successful. Here the milk from which butter is made is kept in large, shallow pans, sometimes on open, temporary shelving, but more frequently in "safes"—a a light wood cupboard with wire gauze or perforated tin panels at the ends, and folding-doors of the same material. Now there is nothing in this, he says, to prevent the exhalations, desquamations, or disease-germs from being absorbed—and nothing possesses absorbent properties more than fresh milk. Or it may only fall on the surface of the milk, from which it, with the cream, is carefully skimmed until sufficient is gathered for churning, when it is made into butter, packed and carried to its home market, from thence to anywhere and everywhere, without ever having been subjected to any influences, either thermal or chemical, to destroy or impair organic life.

Dr. Lichty also seen the mother, who was the housekeeper and only nurse, leave a large wooden bowl full of butter, in which her hands and arms had been immersed nearly to the elbows, and follow him through two adjoining rooms, in which her children were sick with scarlet fever, to give him the history of their illness the night previous, receive directions and instructions, and then return to her butter-packing without stopping to wash her hands. And this butter was sought by local dealers, shipped to city markets, where well-watched and carefully isolated innocents developed those mysterious *de novo* cases of scarlet fever.

Treatment of Nose-Bleed.

In the *North Carolina Medical Journal*, February, 1888, Dr. N. B. Herring gives

some practical hints under the title "Little Things in Medicine." The following is his treatment of epistaxis:

Take a piece of tough, raw, fat, salt pork, cut it wedged shaped, four inches long, half inch thick, and three-quarters of an inch wide. Force it into the bleeding cavity—*clear through into the pharynx*—and the work is done. It is antiseptic, painless, and never fails to stop the hemorrhage. It is easily removed, and the lookers-on are often solicitous to know what you put on the meat to produce such marvellous results. A hint to the wise is sufficient.

Mütter Lectures.

Dr. O. H. Allis will deliver a course of lectures on the Surgical Pathology of the Articulations, on Tuesday and Friday evenings, at eight o'clock, at the College of Physicians, Philadelphia, beginning March 6, and ending April 6.

The Fellows of the College and the medical profession are invited to attend these lectures, which are delivered under the provisions of the will of the late Dr. Mütter, and under the auspices of the College of Physicians of Philadelphia.

The German Crown Prince's Condition.

The following official bulletin from the physicians attending the Crown Prince gives the most exact information about his condition which has been furnished for a long time:

San Remo, March 6, 11 A. M.—In view of the reports published in the press, alleging differences of opinion among the physicians attending the Crown Prince of Germany, the undersigned declare that, as regards their ideas of the nature of the illness, no such divergencies exist. Just as little do they maintain that a dangerous turn in the malady is imminent. The sole responsibility for the conduct and treatment of the case remains, as prior to the recent operation, in the hands of Dr. Mackenzie. In the interest of the august patient, as well as of the peoples who esteem, love and revere him, the doctors once more ask German and foreign papers to abstain from all discussion concerning his illness or the methods or instruments used in his treatment.

The local disturbances in the larynx have not appreciably altered. The wound has healed and the canula lies comfortably. The patient's lungs are in a healthy condition. The cough and expectoration have diminished. The patient's strength is more satisfactory. His appetite is increasing. There is no digestive disorder, no pain on swallowing, and no headache. He sleeps, with interruptions, for hours together.

As Dr. Bergmann's mission has terminated, he will leave shortly. (Signed)

Mackenzie,	Hovell,
Schrader,	Bergmann,
Krause,	Bramann.

Leprosy in England.

The *Brit. Med. Journal*, in its summary of leprosy for the year 1887, says: In the *Journal* of June 11 (p. 1269), Professor Gairdner communicated a very interesting case of the occurrence of leprosy in a boy, the child of British parents, apparently as the result of vaccination from a tainted source. More lately, a discussion has been carried on as to the contagiousness of leprosy, and its communicability by contact and inoculation, as well as by vaccination. Letters have been received from the medical officers of leper asylums in the East which have reopened the whole question; whilst in a letter to the *Times* of November 8, Archdeacon Wright sought to show that leprosy is increasing in this country, and that stringent measures are called for to keep all lepers apart from the healthy. A committee of the Royal College of Physicians has presented a report on this subject (July 15), in which they hold that leprosy is not contagious in the conventional sense of the term, or only so in low degree and under exceptional circumstances, and that compulsory measures of segregation of the affected are not justifiable. In the *Journal* of Nov. 19 (p. 1120), cases are cited from Dr. Monro's work on the *Etiology and History of Leprosy*, which show the nature of the evidence in support of the theory of contagion.

Treatment of Malignant Tumors of the Breast.

In the *Glasgow Med. Journal* January, 1888, Mr. John Fagan, surgeon to the Royal Hospital and Belfast Childrens' Hospital, publishes a paper upon the treatment of tumors of the breast. The following is a summary of his views regarding the treatment of malignant tumors:

"1. That in many of the very worst forms of advanced painful, ulcerating scirrhus, where there is no immediate danger of death from marasmus or visceral complications, the breast may be removed with great benefit and relief to the patient.

2. That all cases of malignant growths of the breast, as soon as they are diagnosticated,

should be removed at once by operation and in the thorough manner I have described.

3. That all doubtful cases should be dealt with in the same way.

4. That all recurrent growths should be removed at their earliest manifestation.

5. That all non-malignant neoplasms, as soon as they show a tendency to enlarge, and especially between the ages of twenty-five and forty years, should be removed without delay."

The following quotation from the writings of Jonathan Hutchinson bears forcibly on this point:—'Too late! too late! is the sentence written, but too legibly on three-fourths of the cases of external cancer concerning which the operating surgeon is consulted. It is a most lamentable pity that it should be so; and the bitterest reflection of all is, that usually a considerable part of the precious time which has been wasted has been passed under professional observation and illusory treatment.'

When the doctrine of the precancerous stage shall he widely adopted, and when surgeons generally shall recognize the propriety—let me say the duty—of opertion for purposes of prevention, then, and I believe not till then, shall we witness a considerable reduction in the mortality of cancer."

Tubercular Laryngitis.

Dr. Henry L. Swain, lecturer on diseases of the throat and ear in Yale College, concludes a long paper on tubercular laryngitis in the *N. Y. Med. Journal*, December 17, 1887, with the following summary of what he has said, which he quotes from Prof. Massie, of Naples:

"1. We are still in want of some remedy or remedies to effect a cure of laryngeal phthisis.

2. Notwithstanding this want, the local treatment of the disease is incumbent on every physician.

3. Many cases quoted by various writers are of extremely hypothetical nature, inasmuch as they have not been a sufficient time under observation.

4. Cocaine, iodoform, iodol, and sublimate are perhaps the best of the local remedies (to which I would add lactic acid, differing from the writer, who doubts its great efficacy)."

A Druggist's Prerogative.

The *National Druggist*, January 15, 1888, says: While on the subject of the responsibilities of druggists under the liquor laws, the decision of Judge Guthrie, of Topeka, Kan., in the case of Trehy *vs.* Holliday, is an important one, as clearly defining the duty of the druggist under certain embarrassing circumstances. Trehy obtained a prescription for gin from a physician who was unknown to the pharmacist, and the latter, knowing the patient to be a habitual drinking man, refused to fill it. Trehy forthwith sued for heavy damages, alleging that his health had been damaged by the failure to get the prescribed "medicine." When the case came up for trial, Judge Guthrie decided that the complainant had no cause for action, and that Holliday, when he refused to give him the liquor, was not simply exercising the discretion left him under the law, but obeyinig the spirit, if not the letter, of the statutes.

Increase of Lunacy in Austria.

On the occasion of the opening of the Session of the Lower Austrian Landtag, the Landmarschall (Count Kinsky) confirmed the great increase of lunacy, remarking that all the country asylums were filled to overflowing, and that a further erection of similar institutions in Kierling-Gugging was necessary. This increase which had been repeatedly confirmed from various quarters, during the last decennium, found its explanation in the difficult struggle for existence, in the exciting haste to become rich, and the unsatisfied struggling and striving after place and power, and in the never-ceasing trouble and anxious care produced by the daily blighting of one hope after another. The so-called embitterment of character gradually degenerated into a mental disturbance; the slightest neurotic disposition led to a disturbance of the mental equilibrium. In men, additional factors were alcoholic abuses; in women, anæmia, and exhaustion of all kinds; in both sexes, strong passions, mental and bodily strain, and a faulty development of the power of mental resistence, which easily led in consequence of hereditary taint to the temporary or even permanent destruction of cerebral equilibrium. An improvement in the sad condition was not to be speedily hoped for, the disease is intimately associated with the solution of great social problems, which only to a slight extent lie within the province of the physician.—*Medical Press and Circular*, December 24, 1887.

Antipyrin in Hemoptysis.

Dr. Olikhoff writes to the *Russkaya Meditzina* that, having seen in some medical journal that antipyrin possesses hemostatic properties, he made use of a solution of

ninety grains in six ounces of water for inhalation in six cases of hemoptysis. He ordered five or six inspirations to be taken through the inhaler every half hour or hour. This had the effect of diminishing the hemoptysis at once, and of rapidly arresting it. And in the same journal, No. 36, 1887, Dr. Olikhoff states that he employed antipyrin with brilliant results in six desperate cases of hemoptysis, after various ordinary hemostatic means had utterly failed. The drug was administered in the shape of a solution of 1½ drachms to 6 ounces of water, which was inhaled every half hour or hour, five or six times a day. The hemorrhage was strikingly diminished in the course of the same day, ceasing altogether on the next one. In all the cases a marked decrease of the (febrile) temperature was also simultaneously observed. All Dr. Olikhoff's patients were suffering from broncho-pneumonia.—*Quarterly Therapeutic Review*, January, 1888.

The Gonococcus in Court.

Some little time ago in Belgium a man was accused of the rape of a little girl. On the clothing of the accused, and also on that of the alleged victim, spots of pus were found and handed over for examination to a physician and a pharmaceutist of the first class. These experts declared the pus to be gonorrhœal; whereupon the defending counsel demanded proof of the presence of gonococci. Dr. Castiaux, Professor of Forensic Medicine at Lille, was therefore called upon to make a fresh examination of the spots, with the object of determining the existence or non-existence of micro-organisms. Dr. Lober, who took part in the examination made pure cultivations of the pus on various media, and finally on sweetened and peptonised agar, and by this means was enabled to confirm the gonorrhœal nature of the pus. —*Medical Press and Circular*, Dec. 28, 1887.

Report on the Health of School Children.

Dr. Moreau Morris, Sanitary Inspector of the New York City Board of Health, makes the suggestion that principals of public schools be required to make a special report every month, for the Board of Health, of the percentages of absence on account of illness, in the several grades of pupils, so that investigation and remedial action, if necessary and practicable, may be had in cases which appear extraordinary, or which may arise from insanitary conditions or mismanagement in the schools, imperfect isolation of contagion, etc. This, as the *Sanitary Era* says, ought to be done everywhere.

NEWS.

—Dr. Edward Jackson has been elected Professor of Diseases of the Eye, in the Philadelphia Polyclinic.

—Dr. John H. Musser has been elected attending physician to the Presbyterian Hospital in Philadelphia.

—An epidemic of measles is raging in Washington City and the Government departments are said to be short of clerks.

—The Medical Department of the Arkansas Industrial University held its commencement March 1, 1888, and graduated 20 men as physicians.

—The death of Prof. Ernst L. Wagner, Director of the Medical Clinic at Leipsic, is announced. He was editor of the *Archiv für Heilkunde.*

—The U. S. Government has decided that certain bulbous-rooted plants, known as "Convallaria," or "Lily of the Valley," are entitled to free entry.

—The Court of Claims has allowed the claim of Dr. John S. Billings $1,500 for mileage, while travelling in Europe under orders from the Secretary of War.

—The Philadelphia Dental College graduated 119 men, Feb. 24, 1888. The Dean, Dr. J. E. Garretson, said that it was the largest class that had ever graduated from any dental college in the world.

—Dr. Henry F. Lyster, of Detroit, has been appointed successor to the late Dr. A. B. Palmer as Professor of the Principles and Practice of Medicine in the Medical Department of the University of Michigan.

—On March 1, fire broke out in the northwest pavilion of the Cincinnati Hospital, driving patients out of their wards, but injuring no one. The fire was caused by the leakage of gas, and broke out in the upper part of the building.

—President Boyles, of the New York Board of Health, said March 1, that there had not been a single case of small-pox in the city since February 25, and only one case on that date. He considered the disease practically stamped out for this season, and attributed this desirable state of affairs to the rigid vaccination of all the tramps and nomadic tenants of low lodging-houses that the Department can lay its hands on. There has also been a marked decrease in diphtheria of late. Scarlatina has somewhat increased, but not to any alarming extent.

HUMOR.

SCENE, a connubial bed. Time, 2 A.M.—Wife, "Charlie! Charlie! do stop snoring. Turn over on your side." (Nudges him. Husband, only half awake, grunts, turns on his side, and continues to snore). Wife remembers a line from an article called "How to prevent Snoring." Gives her husband a second nudge, which elicits another grunt. "Oh, Charlie! If you'd keep your mouth shut you'd be all right." Charlie (still semi-conscious)—"So would you!"

TO BE TAKEN AT BED-TIME.—The following is sent us by Mr. J. C. Spring, of the Bear City Drug Store, Bear City, Ark., who states that it is a *bona fide* prescription, sent in by a registered physician of that region. If any of our readers are tired of life and want to leave this world "a screechin' an' a screamin' for joy," as an old negro preacher once told us concerning his wife, who had "jis' died of de rebilious colic," he might try this at bed-time:

"Podoflin 5 cts. Leptandra 5 cents, ruberb 5 ct. Pownded balsam-phur 5 cts Turpantime 5 cts Niter oz 10. To be mixed and took at bed time."

Mr. Spring volunteers the remark that when any of our readers beat this record for a registered physician anywhere, he will go him one better, which he holds in reserve. —*National Druggist*, February 1, 1888.

BILL NYE AS A SCIENTIST.—He elucidates a knotty point in anatomy for a Louisiana man.—*Mr. William Nye, New York City.—Dear Sir:* Knowing the vast extent of your attainments in the domain of natural science, and being myself an earnest seeker after truth in the same field, I feel free to ask you to explain the meaning of the following sentence, which you will find at page 35, in chapter iii, of a book on "Comparative Anatomy and Physiology," by F. Jeffrey Bell, M.A., Professor of King's College:

"It happens to many gastrulæ that, their blastopore closing up, they develop an investment of cilia on their epiblast and swim about for a time freely in the water."

If you can shed any light upon the meaning of this sentence, you will confer a favor upon, Yours respectfully, JAMES KERSON.

Marksville, La., Nov. 7, 1887.

I understand the above perfectly well, but I do not know that I can make it clear to you through the medium of the press. I would much rather see you personally and explain it to you. If I could take you into my laboratory for an hour or two, I could give you a better idea than I can in a limited space here. Could you not come on to New York and have this matter settled?

Gastrulæ, as you know, are of two classes, viz: malignant and intermittent. It is the first class that is most likely to get their blastopore plugged up. Then trouble begins. Cilia begins to erupt on the epiblast, and microbes break out all over the duplex. You can't be too careful about this. A blastopore, if I've got the right idea of what a blastopore is, should be brought in every night, or the boys may get hold of it and plug it before it is ripe. I would rather see an epiblast of mine, or a blastopore, or a gastrulæ for that matter, in its grave, than mixed up with an investment of cilia or any other doubtful financial matter. BILL NYE. —*New York World.*

OBITUARY.

THOMAS B. LESTER, M.D.

Dr. Thomas B. Lester died at his home in Kansas City, Mo., February 24, 1888. He was graduated from the Missouri Medical College in 1850, and was at one time a Vice-President of the American Medical Association.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from March 4, 1888, to March 10, 1888:

First Lieutenant W. W. Fisher, Assistant Surgeon, sick leave extended one month on surgeon's certificate of disability. S. O. 50, A. G. O., March 2, 1888.

First Lieutenant Paul Shillock, Assistant Surgeon (recently appointed), ordered for duty at Fort Assinniboine, Mont. S. O. 50, A. G. O., March 2, 1888.

Changes in the Medical Corps of the Navy, for the week ending March 10, 1888:

Assistant Surgeon E. P. Stone, detached from the Coast Survey Steamer "Bache" and to Hospital, New York, for treatment.

Assistant Surgeon James F. Keeney, commissioned March 1, 1888.

Surgeon, George R. Brush, ordered to the "Omaha" when "Pensacola" arrives at Aspinwall.

Passed Assistant SurgeonVictor C. B. Means, to the "Omaha" when "Pensacola" arrives at Aspinwall.

Official list of changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ended March 10, 1888:

Hutton,W. H. H., Surgeon. To proceed to Brunswick, Georgia, on special duty, March 5, 1888.

Detailed as president of Board to select site for Gulf Quarantine Station, March 10, 1888.

Carter, H. R., Passed Assistant Surgeon. Detailed as recorder of Board to select site for Gulf Quarantine Station, March 10, 1888.

Wasdin, Eugene, Passed Assistant Surgeon. Granted leave of absence for thirty-days, March 8, 1888.

Bratton, W. D., Assistant Surgeon. Ordered to examination for promotion, March 7, 1888.

WHOLE No. 1621.] MARCH 24, 1888. [VOL. LVIII., No. 12.

PRICE $5.00 PER YEAR. SINGLE NUMBERS 10 CENTS. ESTABLISHED IN 1853 BY S. W. BUTLER, M. D.

PHYSICIANS' ANNOUNCEMENTS of Sale or Purchase or Exchange of Practice, or Books, or Instruments, inserted for two dollars first time, one dollar every succeeding time, space not to exceed one inch.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Clinical Lecture.

OPHTHALMIC CLINIC OF THE JEFFERSON MEDICAL COLLEGE HOSPITAL.

SERVICE OF DR. WILLIAM THOMSON.

[Reported by George F. Souwers, M.D.]

We are about to enter upon the consideration of an operation, which, while it has formed the topic of thought and the subject of lectures and writings of most of the leading ophthalmologists of the world is yet, in certain of its phases, an unsettled matter. Periodically, especially for the past forty years, operators attempt to strike out in new directions in regard to it, and just at this time the procedure seems to be passing through a transitional stage once more. If we take up the books of half a century ago, we find that a method of operation was pursued that has almost been relegated to oblivion. At that day we discover, that, while enucleation or excision of senile cataract was sometimes practiced, yet the adherents of the operation by displacement of the lens were largely in the majority, men of prominence of that day taught and wrote of this method as eminently right. Bretonneau, Velpeau, Malgaigne, Bell, Sichel, Pancoast, Lawrence and Smith, names which to-day seem far distant to us, all advocated and practiced it, and claimed to obtain for that time, very excellent results. We find that one of this distinguished number gave directions for the performance of the operation about as follows: The patient lying down or being seated the surgeon stood either in front or behind him, so that he could always use his right hand; the needle was introduced through the sclerotica, about two lines behind the cornea, and was then directed so as to pierce the posterior and inferior part of the lens; the capsule divided, and then the needle being passed above the lens with its concavity looking downward, a simple movement of depression sufficed to cause the descent of the lens into the vitreous humor; laceration of the cells of the hyaloid before depressing the lens being also advocated. Extraction, pure and simple, was especially advocated for cases of well ascertained hard cataract, particularly when occurring in very prominent eyes, and if under the care of men possessing marked digital dexterity. In that day one of the principal duties of the assistant consisted in properly raising and retaining the upper lid in situ, commonly with his fingers or occasionally with a crude form of speculum, great care being taken to make no pressure upon the eye-ball; in fact one of Velpeau's aids is chargeable with having, by undue pressure, entirely evacuated the contents of an eye-ball. The method of extraction fifty years ago was, in most respects, the counterpart of that of to-day. The corneal incision was, however, of greater extent and made in one of three different directions; the favorite method was one by which the knife made section of the upper half of the cornea; in favor of the procedure was the fact that the aqueous humor did not escape as readily as by either of the other two styles of operation, in one of which the knife made an exterior lateral flap of the cornea, whilst in the third form the cornea was separated from the sclerotic at its lower border, this latter section being the least favored on the score that prolapse of the iris into the wound was much more liable to occur. In considering the operation of to-day we have unfortunately to recognize the fact that there is a constant desire on the part of many operators to needlessly modify the method of removal of the cataractous lens. I must place myself decidedly in the category of those who oppose

what would seem to be the coming or rather resurrecting doctrine, namely, the non-performance of an iridectomy as an essential element in the conduct of the case. Liebricht has attempted a modification of the proceeding which I do not feel is at all warranted; in his method of operating a very large corneal wound is made. We all recognize the circumstance that the cornea is a tissue of comparatively low vitality, or that at least its nourishment is not such as to warrant any extensive interference with its supply; this being an admitted fact by all, it does not seem reasonable to make an extensive flap operation for the purpose of allowing the ready escape of the lens. One of the most serious objections to such a section of the cornea, aside from that already advanced, is the increased tendency which such a large wound has to gap. This large flap plan, it is claimed, allows the escape of the lens without the necessity of an iridectomy, thus preserving the natural shape, symmetry and mobility of the iris, and it is the requirement or non-requirement of this latter operation which is the latest cause of contention among ophthalmic surgeons. My experience in this hospital, where I have performed on an average from twenty-five to thirty cataract extractions a year, in all of which iridectomy was performed, has led me to the conclusion that the best results obtainable are secured by this method. In institutions especially devoted to the treatment of the eye, where trained assistants are constantly at hand to carefully look after the cases, it may be that cases of non-iridectomy do well, or fairly well; but I am satisfied that in those cases which receive but the care of the ordinary general hospital, or the even less trained care of private practice, iridectomy should be one of the integral portions of the operation. In the years from 1881 up to the present day, under full antiseptic precautions, but two of our cases have failed to make a good and thoroughly satisfactory recovery; one of these cases, however, may clearly be placed in the category of accidents after operation, extensive hemorrhages in the eye having been induced by the patient striking his head against an iron pillar, while attempting to walk around the ward before the bandages had been removed from his eyes. The operation of von Graefe was evolved by that celebrated oculist in order to avoid hernia of the iris, and also to give greater light passage in case of complications due to iritic adhesions and pupillary occlusions subsequent to the immediate operation. My experience has taught me that even with a large coloboma a certain number of bands of organized lymph may be formed and interfere to a greater or less extent with the acuity of vision, as well as the appearance of the eye. If this be so with an iridectomy having been performed and thus all the chances of success on the operator's side, how much more liable to an unfortunate issue must be an eye left, in a greater or less degree, to the tender mercies of an iritis? Granting that, as happens at times, adhesive bands are thrown across the pupillary area after operation with iridectomy, it is but a simple matter to introduce a fine needle knife, and turning its cutting edge against the prominent edge of the bands cut them through and allow them to roll out of the line of vision or be absorbed. Very recently I have done this operation on one of our hospital cases where bands interlaced in many different directions, with the happiest results. Where innovations in eye-surgery are manifestly beneficial, I am in hearty accord with the progress of the profession; but I must admit myself conservative where, as in this procedure, I do not feel satisfied of the utility of the method. Personally, I prefer the von Graefe operation, or a slight modification of it. My knife, having a very narrow blade, being entered a little to the outside of the sclero-corneal junction, is directed slightly downward till I have made my puncture, this being at about the upper fourth of the cornea; then the instrument is carried directly across to a corresponding point on the opposite side, for its exit. The knife is now carried upward till about one millimeter from the superior juncture of the sclera and cornea, when the cut is changed in direction to one upward and slightly outward, the knife thus making its exit just at the point of union of the sclerotic and cornea. In most cases a portion of the iris at once falls into the wound, where it is caught by an iridectomy forceps and a portion excised. A crucial incision of the capsule of the lens is then made and the lens at once, by slight pressure from below upwards and a little backwards, makes its exit. All lens detritus viewable is delicately manipulated and removed, after which the following wash is instilled in the eye:

℞ Hydrarg. biniod. ..... gr. j
Potass. iod. ..... gr. x
Aq. rosæ ..... f℥ j

Ten drops of this solution is added to one ounce of water and the eye washed carefully.

This makes, for ophthalmic purposes, one of the most satisfactory of germicides. A few drops of a four grain solution of atropia having been placed in the eye, a light absorbent cotton-dressing is made and held in place

by a bandage extending over both eyes, and terminating in strings or ribbons tied at the back of the head. I may add, that I generally employ a bandage which is knitted out of a fine brown yarn, the width being about three inches, the length, exclusive of the ribbons for tying, about six or seven inches. Frequently, instead of the cotton-dressing, I use strips of surgeon's silk adhesive plaster over the closed lid, the bandage being placed over these. A few drops of atropia are instilled every day, by simply lifting the corner of the bandage and introducing the point of a pipette beneath the lid; as a rule the eye is not examined particularly for three or four days, when it is generally found in very excellent condition. About one month subsequent to the operation glasses are fitted for the near and far point; the cases remain in hospital about ten days, though advised to report occasionally for inspection every few weeks for two or three months.

In the case before us we have an example of what a penetrating blow of the cornea may produce; the young man's eye is in a much more favorable condition than it was a few weeks ago when he first applied to this clinic for relief. Having been struck on the eye, the patient did practically nothing for himself for four or five days; then, becoming alarmed, he applied here. The eye was injected, angry looking and painful; the cornea was hazy and tending to abscess and slough; altogether the case looked very unfavorable. The condition present was almost identical with what we would find in a cellulitis due to erysipelas. The treatment consisted in tapping the minute suppurating points and in keeping the eye thoroughly under the influence of a solution of two grains of eserine to an ounce of water. For what little haziness remains, we shall employ dustings of the cornea with levigated calomel. The sub-carbonate of bismuth has been also suggested for the removal of these leucomatous conditions; but our experience here has been that in some, and nearly all eyes, there is more or less a sense of irritation and grittiness experienced by the patient when bismuth is used, whereas no complaint is made when the mercury salt is employed.

—Dr. William H. Welch will deliver the Cartwright Lectures for 1888, before the Alumni Association of the College of Physicians and Surgeons, New York, April 5 and 12, at 8.30 P.M. His subject will be "General Pathology of Fever."

Communications.

SEX AND CONSUMPTION.

BY THOS. S. SOZINSKEY, M.D., PH.D.,
PHILADELPHIA.

"Our method of discovering the sciences," says Bacon, in the *Novum Organum*, "is such as to leave little to the acuteness and strength of wit." It is to be feared that Bacon's method is not always followed by medical men; it must be obvious to the more critical that in their productions there is very often strong evidence of too much "acuteness and strength of wit." Now, in scarcely any branch of medicine are these qualities more frequently apparent than in that of statistical medical studies; and in no other is the perversion of the inductive method of study more objectionable. Medical statistics may be in themselves more or less defective, but such as they are, they should be studied according to the method of science and for the sole purpose of the discovery of truth.

These remarks, and those following, have been in part suggested by certain statements appearing and reappearing in the journals of the day in regard to the relation of sex to the occurrence of consumption of the lungs. It seems to me that the vast collections of mortality statistics at our disposal should throw a fair amount of light on this subject. It is not a very complex matter. The question is: Do more males than females become affected with consumption? It being a disease which sooner or later proves fatal, the number of deaths would seem at first view to indicate the number of cases. This, however, is not so; for many persons affected with consumption are cut off by intercurrent diseases. Just how large the proportion of those dying in this way may be there is no means for determining, but it is, doubtless, very considerable. And it is safe to say that the proportion is far greater in the young than in the comparatively old; for the reasons that the young are greatly in the majority, and the tendency to such disease is stronger in early than in later life. It would be idle to argue that sex *per se* is accountable for the greater or lesser mortality of men or women from consumption. No doubt sex has something to do with it; for the two sexes differ in strength and otherwise. The mode of life is probably of more significance than the sex. The two are not similarly exposed to influences of the various kinds affecting health. The life of the young woman is apt to be less hygienic than that of

the young man. Among persons no longer young a reverse statement is probably true. Mature men do not as a rule live as healthfully as mature women. Apart from necessary exposure in the struggle for existence, a large proportion of men ruin themselves by dissipation of one kind or another, break themselves down and bring on diseases, consumption being a common one.

The mortality statistics available for the determination of the question of the greater prevalence of consumption in one or the other sex, are generally only those of large communities. The number of applicants for treatment at a dispensary, or the number of inmates of a hospital for chest diseases, or the number of cases a particular physician may have treated, is a poor basis for even an estimate. Women, and especially the young women, are more likely to be treated exclusively at home than men. Then, even the general mortality statistics, if taken in the aggregate, are not likely to indicate very much on the subject in question. The whole number of deaths of men and of women from consumption of the lungs may be equal, and yet it would not follow that the two sexes are equally prone to the disease. This is obvious from preceding statements. It is well to bear in mind that in some communities the number of persons of either sex is not the same. In some of our Eastern States women are considerably in the majority; and hence, other things being equal, one would expect more deaths of women than of men. With correct statistics it is well to study the proportion or ratio of the deaths according to sex, to the population of either sex. The census statistics of the United States being very incomplete, do not enable one to gain a knowledge of the proportion of deaths to the population.

The age of the victims of consumption should be considered; and herein mortality statistics are often defective. In this respect the statistics of our great cities are very defective. One can gather from the statistics of Philadelphia that so many minors and so many adults have died from consumption, but that is all.

The census statistics are the ones of chief value to us in determining the question at issue. And these are somewhat misleading, because there is a greater proportion of deaths unreported of women, and especially of young women, than of men. A few years ago I became interested in the question of the relative frequency of consumption in the sexes at the various periods of life, and contributed an article on the subject to the MEDICAL AND SURGICAL REPORTER, for January 1, 1881. That article was based mainly on the statistics furnished by the United States census of 1870. The outcome of the study was very striking indeed, and should command the attention of every student of this terrible disease. Since the article referred to was published the mortality statistics of the United States census of 1880 have come to hand, and in connection with those of 1870, afford excellent data for comparative study.

The following table gives the mortality of males and of females from consumption of the lungs, at different ages, in the United States, during the census years ending with June, 1870 and 1880:

	1880.		1870.	
Age.	Males.	Females.	Males.	Females.
Under 5	2460	2248	2274	2209
5–10	447	640	459	494
10–15	583	1324	501	1056
15–20	2409	5412	1756	3431
20–25	5312	8491	3938	5138
25–30	4788	7188	3904	4684
30–35	3912	5421	3329	3556
35–40	3769	4560	3262	3215
40–45	3075	3431	2631	2422
45–50	2771	2623	2423	1843
50–55	2481	2119	2130	1655
55–60	2063	1531	1657	1221
60–65	1979	1631	1704	1407
65–70	1629	1399	1341	1172
70–75	1272	1128	1118	993
75–80	839	811	745	696
Over 80	536	608	726	706

The essential features of my remarks on the statistics for 1870 are as follows:

"In persons under five years of age the mortality from consumption of the lungs among males is greater than among females.

"From five to ten years of age females are more liable to have the disease than males.

"Among persons of from ten to fifteen, over twice as many females as males succumb to the disease.

"Among persons of from fifteen to twenty nearly twice as many females as males are destroyed by the disease.

"Consumption of the lungs among persons of from ten to twenty years of age destroys about two females to one male.

"Among persons of from twenty to twenty-five, about a quarter more females than males die of the disease.

"Among persons of from twenty-five to thirty, about a sixth more females than males die from the disease.

"Among persons from thirty to thirty-five, about a twelfth more females than males die from the disease.

"From the age of thirty-five forward there are more deaths of males than females from the disease.

"From forty-five to fifty, from fifty to fifty-five, and from fifty-five to sixty, a third more males than females die from it."

The whole number of deaths of males in the census year was 33,971, and of females 35,925. From these and other figures "it would appear that as a whole there is a considerably larger number of deaths of women than of men from the disease." The figures for 1880 show more conclusively than those for 1870 that more deaths of male than of female children are attributable to consumption of the lungs. As stated already, there are more deaths of women than of men unrecorded. As there are more male than female children, one would expect the aggregate deaths from the disease to be somewhat more. The figures for 1880 indicate a much heavier mortality of females than of males of from five to ten years of age from this disease. The ratio is about three to two. The figures for 1870 show that over twice as many females as of males, ten to fifteen years of age, die from the disease. Those for 1880 show a still greater fatality among females of such age. In 1870 the deaths of females of from fifteen to twenty years of age were not twice as numerous as those of males of the same age. In 1880 they were over twice as numerous. The figures of 1870 show the deaths of persons from the disease, of from ten to twenty years of age, to consist of about two females to one male of the victims. In 1880 there were considerably more than two females to one male. In 1870 there were about a quarter more deaths of women than of men of from twenty to twenty-five years of age, while in 1880 there were over a third more. Of the deaths of persons twenty-five to thirty years of age, there were, in 1870, about a sixth more women than of men, while in 1880 there were about three women to two men.

In 1880 there were about a third more deaths of woman than of men of from thirty to thirty-five years of age, whereas in 1870 there was only about a twelfth more. In 1870 the deaths of men exceeded those of woman among persons over thirty-five years of age. In 1880 the deaths of women are considerably in the majority, until after the age of forty-five years. Among persons over forty-five years of age nearly a quarter more men than women die from consumption of the lungs. Of the deaths attributed to consumption in 1880 there were 40,512 of males and 50,758 of females, or about four of the former to five of the latter. The difference was not so marked in 1870. As the living males in 1880 were 25,518,820 and females 24,636,963, it follows that there were 630 males alive to one death of the same, and 406 females. But it should be remembered that really the relative mortality is much heavier, because the record of deaths is very defective.

The statistics of both 1870 and 1880 show that far more females than males die from consumption of the lungs. In the earlier years of life the mortality of females is shockingly greater than that of males. And were it possible to estimate the number of those who would die early from consumption, if not cut off by intercurrent diseases, the greater prevalence of consumption among females than males would be still more evident. Evidently a theory of the cause of consumption based on the assumption that males are more subject to the disease than females is incorrect. It can have little or nothing to support it save what may spring from "acuteness and strength of wit." The more markedly pectoral character of breathing in women compared with men, might be put down as a cause rather than a preventive of consumption; for it is in the years that females in general favor that character of breathing by tight lacing that consumption is most destructive to them.

Apart from what heredity and the difference in their mode of life may have to do with the matter, it is more than probable that the more delicate constitution of females than of males renders them the more liable to become affected with consumption of the lungs. As is now generally believed, it is largely a disease whose origin is dependent on the state of nutrition of the body. Hence, all the multitudinous causes which tend to produce degeneracy tend to produce consumption, and *vice versâ*. To attempt to trace the disease to the mode of breathing or any other single cause, whether predisposing or exciting, is not very reasonable. Any theory of the kind must rest in the main on "acuteness and strength of wit."

—The *St. James Gazette* states that a Russian officer was recently taken to a hospital in St. Petersburg, suffering with a gun-shot wound in the region of the heart. The officer confessed that he had shot himself in order to avoid shooting the Czar, which he had been ordered to do by a secret society to which he belonged.

THE SEWING-MACHINE AND ITS EVILS.

JAMES BATES, M.D.,
ALLIANCE, OHIO.

In the MEDICAL AND SURGICAL REPORTER, December 10, an editorial mentions the dangers arising from the use of the sewing-machine, especially with reference to diseases of the uterus. For many years I have been giving attention to the operating of the sewing-machine, and have become quite skilled in its use. But since reading your article I have been giving the matter especial attention, with a view of ascertaining wherein these evils lie. I have been long convinced that much misery would be abated if means could be discovered whereby these machines could be run without injury; for that injury does result must be apparent to the most cursory observer. As many of your gynecological readers will doubtless think the following pages overdrawn, incorrect or unimportant, I will to such hazard the remark, that the outrages perpetrated upon women under the cloak of science, make it incumbent upon physicians to "cudgel their brains" to discover, if possible, some means of preventing incurable diseases; and if any one doubts my assertions, let him take up the "wage of battle" and prove them false. I assert that very many uterine ailments, especially in the unmarried, are caused by the constant use of the sewing-machine; and those not primarily so caused, are secondarily very much aggravated by its use. Any one can easily experiment with a sewing-machine, for nearly every dwelling has one; and as the general principles of their operation are the same, no difficulty will be found in proving whether my position is well or ill-founded. Suppose a woman of ordinary stature, seated on a common cane or "Windsor" chair, with both feet on the pedals. In this position the knees are almost, or quite, on a level with the superior surface of the thighs. From constriction of the corset, the abdominal parieties below the umbilical region, are pressed upon the surface of the thighs; hence any movement of the knees in a perpendicular direction must either compress or relax the abdominal walls. In addition, the motion necessary to propel the machine, calls into play several muscles, notably the quadriceps extensor and sartorious of the thigh, and the tibialis anticus and gastrocnemii of the leg, not to speak of several in the foot. The pedals of nearly all machines are so arranged that two motions are necessary to "work" them, namely, up and down; thus differing essentially from the old-fashioned spinning-wheel treadles, which went up of itself, and only required to be pressed down. Morever, in spinning only one foot was used, while the sewing-machine requires both feet. The axis on which the treadle works is so placed that the instep is exactly over it, and the feet when at rest are in a horizontal and natural position; but when the machine is in motion the thighs are pressed hard against the abdomen once for every revolution of the fly-wheel. If the machine is running slowly no evil is apparent, but when it runs with great rapidity, as it nearly always does, the contents of the abdomen, such as bladder, uterus and viscera, generally must get quite a jolting. Also, the action of the muscles of the thighs, especially at their insertion in the neighborhood of the pelvis, would necessarily produce exhilaration, if not excitement of the generative organs; because when the knees are together, if elevated (to counteract the pressure of the abdomen, which would tend to separate the thighs), another set of muscles are called into play, which have rather a close relation to the external genitals. These muscles are the adductors. If the operator could sit in an upright position this condition of things might be borne, but to be able to see her delicate work, she must bend her body forward, thereby enhancing very greatly the just mentioned evils. The abdomen is subjected to still greater pressure, and of course the enclosed organs must suffer in proportion.

Machines as a rule are hard running from a variety of causes. Women are usually only anxious that the machine should do good work; and though it may require all her force to run it, exhausting her thereby, yet if the stitching is correct, all other defects are condoned. Machines become gummy easily from dust and shreds of cloth getting mixed with the oil, and as very few women have much mechanical *conceit*, (I say conceit advisedly), machines so hampered are seldom if ever cleaned. Without good oil, well applied, no machinery will run easily. Fear of soiling goods on the one hand, and pure carelessness on the other permit many good machines to run badly. The tension of the belt has much to do with the easy running of sewing-machines. The tighter the belt the more difficult it will be to run the machine. To make the belt loose enough to run easily the machine must be in good condition, or the belt will slip on the pulley. In so far, we do not see that the machine is always to blame for the evils ascribed to it. But if the

sewing woman were a mechanic, cleaned her machine regularly, kept it lubricated with the best sperm oil, saw that the belt-tension was correct, and in fact got everything out of the machine in the best and most workman-like manner, yet if her usual position at the machine is mantained, all this would only modify, not cure the evil. The machine itself then is at fault, partly in construction, partly in position. The watch-maker is compelled to so cover the works of the time-piece that dust and dirt can reach them only by the grossest carelessness. Inventors generally endeavor to put the propelling power on the long arm of the lever. But in the sewing machine, dust, dirt, shreds and oil are allowed free access, and while the feet propel the short arm, the coupling rod and machinery attend to the long arm of the lever. The belt is of so narrow a surface, as to require too much tension to move the machinery at all.

But in the position of the operator lies the greatest defect. A woman of medium stature seated at a machine, has the thigh and leg forming a right angle at the knee, while the leg and foot alternately form an obtuse and acute angle at the malleolus. The operating of the treadles for any length of time will exhaust the posterior muscles of the leg from want of purchase at their superior extremity. These muscles, especially the gastrocnemii, being intended by nature to be operated with the femur and tibia in direct line. On the other hand, the anterior muscles of the leg, from too much tension can with difficulty contract or relax sufficiently to materially assist the former set of muscles. In fact the quadriceps extensor is required to raise the foot. Except the adductors and quadriceps extensor the muscles of the thigh are nearly at rest, and are injurious only from the irritation produced by pressure. The adductors from their attachment to the pubes and ischium would in strong contraction, have a tendency to excite the sexual feeling, while the pressure of the thighs would so disarrange the viscera, that we could easily imagine prolapsus, metritis, cystitis, even erythism and orgasm if you please, ending in complete wrecking of the whole system. With the foregoing array of difficulties attending the use of the sewing-machine, is it any wonder that so many otherwise healthy women should succumb to its baleful, health-destroying influences? Yet the matter can be remedied.

There are three methods by which these dangers could be almost, if not, quite, altogether avoided. First, in improvement in the machine; second, in improvement in the chair; and third, in improvement in the position of the operator. Usually, unless of small stature, a women when seated at the machine on a common chair has the knees on a level with the thighs, and directly under the needle-bar, requiring the operator to stoop forward in order to see the work. To overcome this defect, a machine should be made so that the needle-bar would be near enough to the operator to allow her to sit in an easy and natural position, *i.e.*, within six or eight inches of the body, and the treadles so placed that her lower extremities would be nearly in a straight line at the knees. To accomplish this a radical change would have to be made in all machines, old and new, entailing great expense, which of course, the very persons most needing help could not afford. The belief prevails that sewing-machines are nearly, if not quite perfect, yet while all other parts have from year to year been improved, the method of driving the machine is essentially the same as it was under Howe's first patent. He will be a public benefactor who soon makes an advancement in this regard.

The second method of avoiding the evils incident to sewing-machines will be found more practicable, at least with regard to expense. A common chair, if perfectly flat on its upper surface, and cushioned, is perhaps the best seat commonly found in our households for a woman to occupy while at the machine. A chair hollowed out in the seat or a cane-seated chair, from the undue pressure of the anterior ridge must do harm from cramping the muscles or nerves of the posterior surface of the thighs. Several years ago, in a number of the MED. AND SURG. REPORTER, a writer called attention to the ease with which a sewing-machine could be run, if the operator would sit on a chair or stool slanted upwards and backwards with a rise of about four inches to the foot. Having given this hint a thorough trial and having had the experience of a number of others, I can safely say that the suggestion is a good one. Without going into any extended argument, I will simply add that it possesses all the advantages with none of the disadvantages of the common chair, and I know no better stool for this purpose than Briggs's organ-stool, which by a simple adjustment can be raised or lowered, to suit tall or short persons, yet with the proper inclination. There is, however, one difficulty connected with this method. To get a good purchase on the treadles the seat must be

comparatively high, thus taking the work further away from the eyes of the operator. But good though it be, will women generally adopt this method? No! And why? Because when a woman wishes to sew she picks up the first chair that comes to hand, and is slow to take up new notions unless it be in way of adornment. Then we must look around for some manner in which she can operate her machine without injury to her health, and yet retain the same machine and chair; which brings me to the third and last method, namely, the *position* which the operator occupies at the machine.

Many of our manufacturers advertise their machines with pictures of girls of tender years operating them with apparent ease, the same little girls having exceptionally round cheeks, bright eyes and rounded arms, leaving the inference to be drawn that their particular machine runs so easily that even a little girl can retain her usual health in operating it. And there is no reason why this should not be true. A new machine, well oiled, will, as a rule, almost run itself, and hence requires but little power.

Every woman whom it has been my privilege to see operating a machine, and my opportunities in this direction have been ample, invariably uses both feet to propel it, giving as an excuse that the machine runs so hard as to require that much force. We have endeavored to show that if properly cared for a machine can be run with very little power. I will go further, and say that the machine which cannot be run with one foot by any woman in average health, is not fit to be run at all. We will suppose a woman seated at the machine, one foot on the treadles the other on the floor, the knees apart, the adductors at rest, the abdomen not pressed unduly upon, the generative organs neither irritated nor disarranged, the machine running so easily that over-exertion of the muscles is at a minimum, and we have a condition of things which will allow her to sit in a common chair and operate the present sewing machine with comparatively little detriment to her health. I am not stating a supposition, but a fact which has stood the test of thorough trial, when I say that if a woman will use one foot to propel the sewing-machine, and alternate the foot as occasion requires, very many of the irritative diseases incident to her sex would be abated. I also am convinced, that when running the machine no corset should be tolerated, as the loosest corset is too tight when using the lower extremities in a sitting posture.

A THOUGHT ON THE DESTINY OF ALCOHOL IN THE BODY.

BY THOS. J. MAYS, M.D.,

PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC.

I do not believe that the fact that a large amount of alcohol can be taken under certain circumstances without producing the least intoxication, has ever escaped the attention of the observant physician. For example, a person who is extremely sensitive to the narcotic effects of alcohol, i. e., one in whom a half teaspoonful dose of brandy will produce the characteristic symptoms of narcosis, such as weakness in the legs, flushing of the face, etc., receives a severe shock, as from an injury, and may then be able to take the same preparation in two or three tablespoonful doses without experiencing the slightest inebriation, but on the contrary will be materially benefitted by it. Or, take a case of croupous pneumonia. In this disease it is well-known that at, or about the period of crisis, alcoholic liquors can be literally poured down the throat of the sufferer without producing any intoxication whatever. I have known such cases where more than a quart of the best brandy was consumed in less than twenty-four hours with nothing but what was believed to be the very best results. There are also records of many cases of snake-bites in which phenomenally large quantities of brandy and whiskey were administered and apparently without any alcoholic symptoms.

Now what becomes of alcohol in such enormous doses? We think this agent is entirely anomalous in this respect, as well as in its action. It is true that in cases of idiosyncrasy, or in tetanus and acute mania, the poison line of morphine is somewhat widened, but in no instance can it be given *ad libitum* like alcohol. Strychnine, atropine, curare, veratrum viride, cocaine, digitalis, and most other vegetable alkaloids must be given in reduced doses so soon as they begin to exert their physiological effects. The large doses in which morphine, and several other drugs are tolerated, can be explained by the well-known physiological law, that a nerve when intensely irritated or exhausted from any cause is less impressible to incidental forces than a healthy nerve. The action of morphine is, however, fundamentally different from that of alcohol, inasmuch as it undergoes no change in the body, and therefore acts by its presence, or through its mechanical influence; while on the other hand it is positively established that alcohol is decom-

posed by the animal economy, and therefore has a chemical action.

From a clinical standpoint, therefore, the only rational explanation which can be given of this singular behavior of alcohol is, that it furnishes some force to the body which is utilized in the same manner as food force is. During great prostration, or extreme depression, just as in pressing hunger, the demand for this force is great and urgent, but in ordinary health it is small and can probably be best supplied by food. Unless this extraordinary action of alcohol can be accounted for on other grounds by our abstemious friends, we think there is much reason for the belief that it has no other but a food action.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 1, 1888.

The President, A. Jacobi, M.D., in the chair.

Should We Treat Syphilis During the Primary Stages.

Dr. Edward B. Bronson read the first scientific paper of the evening, bearing the above title. He explained that by the term preventive treatment was not necessarily meant abortive treatment, but all measures, which in any degree abridged the course of the disease and ameliorated its effects upon the constitution. He showed that in as much as we do not know the essential nature of syphilis, and we have no radical treatment, we must, in looking for new and more effective means of combating it, be guided to some extent by theoretical considerations. He asked the question, if the indications thus far afforded by our imperfect knowledge of syphilis were such as to render any form of preventive treatment in the primary stage unavailing and absolutely hopeless; for such was the view entertained by many physicians. There were two ways of approaching this question, the one theoretical and the other empirical.

No theory explained syphilis so satisfactorily as that which attributed it to the presence and growth in the tissues of a specific micro-organism. But if this theory could be established, it would by no means make certain that preventive methods would prove successful.

Dr. Bronson thought theory and facts pointed to a temporary sojourn of the syphilitic virus in the region where it was first implanted, and during that period the disease was local, not constitutional. From here it sooner or later contaminated the neighboring lymphatic glands, and then passed to the general system. The author cited some objections which had been raised to this view, which he thought were without foundation, and then proceeded to show the inefficacy of proposed methods of treatment during the primary stage of the affection. The principal measures proposed had been excision and cauterization of the initial lesion. Briefly reviewing the history of these measures, he came to the conclusion, as many other distinguished syphilographers had done, that they had not been successful, and that in the nature of things they could not be. The basis for this opinion was the fact that the disease had become general, or affected glands which would escape the surgeon's knife or cautery, before the development of the initial lesion, or the time at which the treatment could be instituted.

He then spoke of the objections which had been offered against general medication during the primary stage. The chief one had been that it was indirect, for, as long as the affection remained local, it was extremely doubtful whether medicine taken internally would reach and destroy the localized virus. The author reasoned that the remedy so much relied upon in the general treatment of syphilis would be more likely to prove a germicide to the syphilitic micro-organism if applied locally during the primary stage than if it were to act by passing through the general system. This view was based on theoretical grounds, and on such grounds he commended it to the consideration of those who had occasion to treat this disease.

The method of employing the drug (mercury) was both by inunctions and by hypodermic injections into the glands in the neighborhood of the initial sore. The injections consisted of not more than one one-hundredth of a grain. He preferred mercurial soap to mercurial ointment for rubbing into the skin. It might be said that this regional treatment was also constitutional treatment, as in a degree it was, but it was something more. Better this, the author thought, than to let the case go on without lending the patient any possible hope. While the treatment was recommended on theoretical grounds, yet he had employed it in certain cases, although the diagnosis and method of applying the treatment were so uncertain as not to justify any conclusions.

Dr. E. L. Keyes said he would have been much interested to hear the results of experiments with this form of treatment. In general he was opposed to constitutional treatment during the primary stage of syphilis for the reason that it rendered its after progress irregular. Excision and cauterization had, he believed, failed in every instance to cut short the disease, and he doubted whether this local treatment with mercury would prove more effectual. The virus had entered the general system before it could be reached by local measures.

Dr. R. W. Taylor held the same views as Dr. Keyes, that general treatment during the primary stage of syphilis was objectionable, as it rendered the future progress of syphilis irregular; the diagnosis remained uncertain until the secondary lesions presented, and if by constitutional treatment during the primary stage such secondary lesions were averted, the patient would not feel convinced that he had syphilis, and would prove intractable; yet the tertiary symptoms were as likely to develop in all their severity as if the disease had taken its usual course, producing the eruption, etc., of the secondary stage. He believed that syphilis was at first a local affection, but he doubted the efficacy of such proposed local treatment. Certainly excision and cauterization had, in his opinion, failed to abort a single case. Then he thought injections of mercurial solution in the glands on the thigh would, if the solution were of sufficient strength to be efficacious as a germicide, produce ulcers. Such had been his experience.

The President compared syphilis with infectious diseases regarding which more was known, particularly diphtheria, and thought a lesson might be learned therefrom. In diphtheria the poison might be local, and it might enter the general system and cause a constitutional disease; it usually entered by way of the lymphatics, but it sometimes found its way to the general circulation directly through the blood-vessels in the neighborhood of the local disease.

A paper by Mr. Bernard Roth, F.R.C.S.E., on

The Treatment of Flat-Foot,

was read by Dr. V. P. Gibney. The author said he was glad to comply with Dr. Gibney's request to contribute to a symposium on this subject, and the more so because his views had changed in some particulars since he wrote an article on flat-foot in Heath's Dictionary of Practical Surgery two years ago. The term flat-foot was a broad one; the cases should be classified clinically if surgeons would come to an agreement regarding treatment. Mr. Roth divided the cases into three classes: 1. Those in which it was possible to restore the foot to the normal situation without mechanical or operative measures. 2. Those in which the foot had become so fixed in its abnormal position by shortened ligaments and tendons, and changes in the articulating surfaces, that it could not be restored without operative measures or *brisement forcé*. 3. Intermediate cases, in which partial restoration of the tarsal arch was possible without *brisement forcé*.

The author had observed that all infants had flat-foot, but when they stood and ran about a few months the arch developed with the development of the muscles on the anterior aspect of the leg. He always assured anxious mothers that there was no cause for their fears in these cases. He believed with Mr. Thomas that the muscles acting upon the foot had their insertions favorable for the support and development of the tarsal arch. Anything which tended to weaken those muscles predisposed to flat-foot. Flat-foot was often associated with knock-knee, and was liable to occur when an injury to one leg caused most of the weight of the body to be thrown upon the other.

In the treatment of the deformity the surgeon had in mind the restoration of the depressed arch, and the development of the muscles which tended to form and sustain that arch. Practically the treatment resolved itself into mechanical and surgical measures for restoring and sustaining the arch, and into therapeutic means for strengthening the muscles.

Regarding mechanical measures, the author said that during the last eighteen months he had discarded pads, and he no longer insisted on wearing a laced boot. He had the shoe made to fit the foot, and the sole and heel so shaped as to direct the axis of the tibia toward the outer aspect of the foot. His reason for doing this was founded on Mr. Thomas's explanation of the formation of the arch, which he believed to be the true explanation, namely, that the weight of the body transmitted through the tibia was expended upon the inner aspect of the arch, and that the arch was enabled to retain its shape by the action of the muscles; when the muscles became weakened, the weight of the body being transmitted through the tibia to the inner aspect of the arch, that arch broke down, and the patient walked upon the inside of the foot. A quarter to half an inch was added to the inner margin of the heel and sole. In the second class of cases *brisement*

forcé should be resorted to preferably according to Thomas's method, and then the cases should be treated as in class one.

The author then described methods for developing the muscles of the leg going to support the arch, consisting in passive and active gymnastic exercises, including walking on the toes a short distance, say fifty feet, after each meal.

The paper was discussed by Drs. Ridlon and Phelps.

The Tariff on Medicines and Surgical Instruments.

A resolution was passed petitioning Congress to remove the import duty on medicines, surgical instruments and apparatus.

Reports of Clinics.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

GYNECOLOGICAL CLINIC—PROF. GOODELL.

Ovarian Tumor.

This woman is 43 years old. I need not call your attention to the enormous tumor from which she seeks relief at our hands. The history of her trouble dates back a period of four years. She first noticed occasional cramps occurring in the lower part of the abdomen, and these were soon accompanied by abdominal swelling. She has not seen her menses for three years. She has lost flesh, her face has become wrinkled and wears a pinched expression, which experience will teach you is strongly suggestive of ovarian disturbance. She has been tapped six times in all, between eight and nine gallons of fluid being withdrawn at each operation.

Let us examine the tumor together. The abdomen is enormously distended, and dilated veins may be traced over its entire surface. On palpation we find fluctuation unusually well defined, and dulness on percussion until we reach a point about three inches above the umbilicus. Here it is resonant all the way up to the ensiform cartilage. Below this is an apparently solid tumor, which gives the sense of ballottement; that is to say, it yields before the finger, as if floating in a fluid, and then returns to the finger with a slight tap. This means that, apart from the tumor, ascitic fluid is present. On transferring our attention to the vulva, we find the vagina completely everted, distended by the ascitic fluid, and exhibiting in consequence an appearance not unlike the male scrotum. In the centre of it is the os uteri, into which I pass the sound fully five inches, showing hypertrophic enlongation of the womb.

Now we are ready to make a diagnosis, and we pronounce the tumor to be ovarian for the following reasons: 1st. The patient has not menstruated for three years, and this fact may additionally be regarded as strong evidence that both ovaries are involved. 2d. The swelling began within the pelvic cavity and extended upwards, lifting the intestines as it advanced. 3d. Ovarian tumors are those of most common occurrence. 4th. It is not a fibroid, because, among other reasons, the menses have ceased here, while the development of a fibroid would have made them more profuse.

Is the tumor malignant? The facts that it began with considerable pain, that we have ascites present, and that both ovaries are involved, might justify us in so thinking. There are some arguments, however, opposed to this supposition. In the first place, the history of the woman's condition covers a period of four years, which is much longer than the usual history of a malignant growth. (It might, however, be a sarcoma, these tumors being sometimes comparatively slow in their progress). Again, the ascites, which is here present, may have proceeded from a papilloma. Very often these cauliflower-like excrescences push their way into the peritoneal sac through the wall of an ovarian cyst, and secrete a prodigious amount of fluid. I shall operate on this patient within the next few days.*

Nervous Abdominal Pulsation Simulating Aneurism.

This patient has just presented herself. In answer to my question as to why she comes to us, she places her hand over the region of her stomach and says that she has a constant throbbing and pulsation there, which has been

*This woman was operated upon a few days later before a ward class. The tumor proved to be a proliferous cyst of the right ovary, with omental adhesions. It was surgically a solid tumor, and could not be reduced in size, even by breaking up the thousands of daughter cysts contained within it. The incision, therefore, had to be a long one, needing twenty-four sutures to close it. The parietal peritoneum was greatly thickened, and the ascitic fluid very abundant. The emptied cyst weighed sixteen pounds; the fluid from it and from he abdominal cavity together weighed eighty-three pounds; the total weight being ninety-nine pounds. A drainage tube was put in, which was removed in forty-eight hours. Since the operation the patient has done well, the temperature reaching just 100° only once.

called an aneurism by several physicians. I am glad to be able to examine this case with you, for it is one of a class that often proves very puzzling. A number of cases are sent to me each year presenting many symptoms which, at first glance, are strongly suggestive of abdominal aneurism. They are almost invariably women of the nervous diathesis, sensitive and highly emotional.

This woman is 24 years old, single, and a domestic servant. She has felt her present sensations for something over two years. At first her symptoms were chiefly those produced by an ordinary dyspepsia, but, in time, these were accompanied by the throbbing which she now complains of and which gradually become more noticeable and more annoying. At present her appetite is fair, but the process of digestion is somewhat painful, and is accompanied by frequent regurgitation of the gastric contents. Flatulence exists, and her bowels are very costive. Her menstrual periods are regular, but the flow is scant and is always attended by pain, and she is very nervous. We find the uterus retroverted, slightly flexed, and giving a measurement of plus three inches. This increase is due to the long-standing retroversion and its consequent dysmenorrhœa. The womb being practically turned up-side down has become gorged with blood and has undergone a gradual hypertrophy. On examining the epigastric region in which lies her chief source of discomfort, we find what seems to be a pulsating tumor. It gives a tense, hard feeling to the hand, which rises under it with every stroke of the heart, as all of you can plainly see for yourselves. I cannot, however, detect any thrill. Now, gentlemen, I do not believe that this is an aneurism, in fact, I am confident it is not. In examining cases like this you will frequently find the rectus muscle a great obstacle in your way and very often the cause of your falling into error. Many women involuntarily contract this muscle at the moment of examination, and throw it into such a rigid condition that it gives to the touch the sense of a tumor, and seriously interferes with any manipulation of the viscera beneath it. At the same time, while the hand is lying on it, it will rise and fall in response to each impulse of the underlying aorta, and will so lead an incautious diagnostician into believing in the existence of an abdominal aneurism. An aneurism, however, would be accompanied by pain, it would be likely to increase steadily in size, and would convey to the hand that peculiar thrill which we fail to find here. Moreover, it is to be remembered that in some women aneurisms are extremely uncommon. If I should etherize this patient the rectus would relax and so remove any uncertainty of diagnosis at once, but I can obtain this same result in a less direct way. Just as a conjurer fires off his pistol to distract the attention of his audience away from his trick, so I shall fire off my pistol, but in another way. I distract the woman's attention from everything else by making a uterine examination, and while doing this with my left hand, my right, unnoticed by the patient, is placed upon the now relaxed rectus muscle and is pressed close down upon the aorta. This vessel throughout its abdominal course, is found of uniform calibre and quite free from any aneurismal dilatation.

Now, what shall we do for this woman? In the first place she shall have a laxative pill, and a very excellent combination for this purpose is found in the pil. aloinæ, belladonnæ, and strychniæ, which is kept in stock by most druggists. The laxative spring waters may be of temporary benefit in cases of habitual constipation such as this, but they soon loose their effect, and the quantity taken has to be increased. This pill which I recommend to you, however, restores tone and energy to the paretic muscular layer of the intestinal walls, and, so far from having to be increased, may gradually be reduced in frequency of administration, and finally stopped altogether. In addition I shall put her on the following mixture, which will act as a general systemic tonic, and coincidently, as a nervous sedative:

℞ Tr. digitalis..... .....f℥iiss
Ammon. chlorid.....℥ij
Ammon. bromid ....ʒss
Infus. gentian.....ad f℥vj
M. S.—Dessertspoonful t.i.d.

—In a paper read before the Gynecological Section at the Sixtieth Congress of German Naturalists and Physicians, Wiedov (*Annales de Gynécologie*, January, 1888) reported five cases of albuminuria in women, in which he demonstrated that the placenta presented the lesions which have been already noted by Fehling. These lesions consist in infarcts, which are to be met with both upon the fœtal and maternal surfaces of the placenta. Fehling stated that in 800 pregnant women he had found eighteen who had albumin in their urine. In all of these cases the placenta presented more or less numerous characteristic white infarcts. As to their origin, Fehling agrees with the opinion of Scanzoni, that in a large number of the cases they are the result of hemorrhage.

Periscope.

Treatment of Intussusception Without Operation.

In the *Brooklyn Medical Journal*, February, 1888, Dr. G. R. Butler reports a case of intussusception which was relieved by hydrostatic pressure. The patient was a little girl three years old, who had suffered for ten days from slight bronchitis and constipation. The latter had been easily relieved with common domestic remedies until thirty-six hours before Dr. Butler's visit. The bowels were then obstinately constipated. During the thirty-six hours nearly three bottles of the ordinary solution of magnesium citrate had been given without result, except that they caused tenesmus and discharges of mucus with small amount of feces. The stools contained no blood. Paroxysmal abdominal pain had occurred, gradually increasing in severity. Vomiting began twenty-four hours previously, and at the time of his visit the ejected matter had a slight fecal odor. The child had eaten nothing, the face was pale and had an anxious look, skin cool and moist, pulse accelerated, temperature 99°. The abdomen was distended and tympanitic, with a special point of tenderness to the left of, and on a level with, the umbilicus. At this point there was a sense of resistance on palpation. It was not possible to accurately outline a tumor.

The child was placed across its mother's lap and the nates elevated. A soft catheter attached to a fountain syringe was then introduced four or five inches into the rectum, meeting with no opposition. Tepid water was slowly injected until the bowel was thought to be distended to the point of safety. Some of the fluid escaped by the side of the tube, but about thirty-five ounces probably entered. The child was then placed upon the left side, with the hips elevated by a pillow. The enema was retained, and the child soon fell asleep, and slept six hours. On awaking, it passed the injected fluid with a moderate amount of fecal matter. Pain and vomiting had ceased. It rested quietly during the night. The next morning a natural and copious movement of the bowels occurred without pain. The child had regained its normal appearance and spirits. No further trouble of any kind was experienced.

In the *Lancet*, Feb. 18, 1888, Dr. Cheadle reports a case of intussusception which occurred in a slightly rickety infant fifteen months old. In this case the child vomited several times, and the passage of blood from the bowel was a frequent and prominent symptom. A tumor was unmistakably outlined by rectal examination. There was much pain and great straining. The rectum was gradually distended by inflating it with air from a Higginson's syringe, and the tumor manipulated through the abdominal walls. Recovery followed. Dr. Cheadle says that this is his third successive case in which the intussusception has been reduced by inflation, and that Dr. Barlow has had a fourth. Early diagnosis and prompt employment of the inflation are the essentials to success.

In the *Lancet*, February 25, 1888, Dr. Goodhart reports still another case, occuring in a child eight months old, in which reduction of the intussusception was effected by means of an enema of two pints of warm boracid acid solution, five grains to the ounce, which was injected with Lund's apparatus. In this case the child suffered with convulsions; the stools were bloody, but the blood was not admixed with mucus, and was not frothy. A sausage shaped tumor could be outlined.

Poisoning with Antipyrine.

In the *Lancet*, February 25, 1888, Dr. Oscar Jennings reports a case of poisoning with antipyrine. The patient was a woman 67 years old, who was of gouty ancestry and suffered with swelling of the hands, without positive pain, but with sensations of pricking, which interfered somewhat with the use of the hands. She was given 37½ grains of antipyrine a day for eight days, when the skin of her arms became covered with erythematous patches; her eyes at the same time became uncomfortable. The following night she scarcely slept at all; the feet were icy cold; there was no nausea, and no giddiness. The next day her face was red and extraordinarily swollen, so as to almost close the eyes, just leaving a narrow slit for vision. The rash was general and of the color of pomegranate, and was arranged in patches the size of a three-penny piece, separated from each other by slight but distinct intervals. The condition gave rise to no suffering, there was only slight itching, but the patient felt as if "the inside of the body was filled with ice." There was irritation of the nasal fossæ and hoarseness of the voice; the pulse was twice as fast as usual but the temperature was lowered. There was slight buzzing in the ears. The symptoms gradually disappeared, but the patient still suffers from considerable prostration and sensations of cold.

Dr. Jennings says that, since encountering the case just cited, the following have been

related to him: Mrs. Y., was treated with antipyrine in order to be *radically* cured of rheumatic pains. She was ordered 75 grains a day. "The second day," writes Miss X., "my friends went to see this lady, who is one of the most intelligent, one of the most witty, and one of the most charming women in Paris. They found her with her head between her hands, the elbows resting upon the knees, rocking backwards and forwards, repeating incessantly, 'I don't know what is the matter with me; I remember nothing; I am becoming like an idiot; I am going mad.' She was subsequently confined to her bed with severe gastro-enteritis for six weeks, and kept her room for three months. Lately she has improved, and has recovered her lost intelligence.

Mrs. Z. was treated with antipyrine. "Her body swelled, as did also the inside of the throat, which was obstructed to such an extent that for six hours she was threatened with suffocation. The skin was covered with red spots, without itching, and the perspiration dripped off the extremities of the fingers."

Transplantation of the Cornea.

In a further communication upon transplantation of the cornea, which is contained in the Report of the Ophthalmological Society of Heidelberg, 1887, S. 30, Von Hippel states that he has succeeded in two cases of leucoma of the cornea in which Descemet's membrane was not opaque, in transplanting the rabbit's cornea upon the human eye. By means of a specially constructed knife the central leucoma upon the patient's cornea was excised in a section of 4 min. (.159 inch) diameter down to Descemet's membrane. A segment of the same size taken from the rabbit's cornea was then transplanted upon the patient's eye, and these united immediately and remained transparent. This patient who before could count fingers only at a distance of 6½ feet, now has a vision of $\frac{20}{200}$. Up to the present time, one year and nine months after the operation, the transplanted segment has not become cloudy. A gray reflex is returned upon focal illumination, but this is brought about by the different index of refraction of the rabbit's cornea and the most posterior layers of the human cornea, which were left behind; at the surface of junction of the two, the light is strongly reflected.

In the second case, in which a serpiginous ulcer had been followed by a central leucoma, a piece of cornea was transplanted in the same way. This also united and remained transparent. Vision had risen to $\frac{1}{10}$. —*Centralblatt f.d. med. Wissensch.*, January 28, 1888.

Syrup of Tar in Winter Cough.

In the *British Med. Journal*, March 3, 1888, Dr. William Murrell says that tar is undoubtedly one of the best remedies for chronic bronchitis and winter cough. He uses the syrupus picis liquidæ of the U. S. Pharmacopœia. With the addition of a few drops of ammonia or other alkali the syrup can be prepared of almost any desired strength of tar. He usually gives it in doses of from two to four drachms every three hours, or even oftener. If disagreeable to take, it may be flavored with syrup of wild cherry. The efficacy of the combination may be greatly increased by the addition of a little apomorphine. Six minims of a two per cent. solution may, he says, be given frequently without exciting nausea. During the past two years he has used this method of treatment in nearly a hundred cases of chronic bronchitis and winter cough, and has every reason to be satisfied with the result. The cough is relieved, expectoration is rendered easier, and the patient usually sleeps well at night. The syrup of tar alone without the apomorphine is admirably adapted to the treatment of the coughs and colds of children, and has none of the disadvantages of preparations containing opiates.

Guiacol in Phthisis.

At a meeting of the Society for Internal Medicine, of Berlin, February 6, 1888, Dr. Fraentzel made some remarks upon the use of guiacol in phthisis. He coincides with the opinion previously expressed to him by Dr. Penzoldt, of Erlangen, that guiacol is the active constituent of creasote; and he employs it in the same doses in which he gave the latter. He uses a formula which is approximately represented by the following mixture:

Guiacol	f ʒj
Tinct. gentianæ	f ʒij
Alcoholis	f ℥j ♏clx
Vini Xerici (Sherry) q. s. ad	f ℥v

M. Sig.—Take a teaspoonful two or three times a day in a wineglassful of water.

Fraentzel thinks the drug is better borne by the stomach when given in this mixture than when given in capsules or with syrup of tolu. Although his experience with it is as yet limited, he advises its employment in preference to creasote.—*Deutsche med. Wochenschrift*, Feb. 16, 1888.

Sequel to a Case of Ligature of the Carotid.

At a meeting of the Clinical Society of London, Feb. 24, 1888, Mr. Holmes read some notes which formed the sequel to an old case of ligature of the carotid artery, which was published in the ninth and tenth volumes of the Society's Transactions as one of distal ligature of the left carotid for aortic aneurism. The patient survived the operation for twelve years, and then died of phthisis. The *post-mortem* examination proved that the thrill, bruit, and pulsation, which were thought to be caused by aneurism of the aorta, depended on stenosis of the valves of the pulmonary artery, with dilatation of its left branch. There had been weakness and occasionally total absence of pulse in the left arm, but the cause of this was not explained by the autopsy, which had been somewhat hurriedly made. The aorta and its branches were healthy as far as they were examined. The left carotid was obliterated in its whole extent. As the case had been used in discussing the propriety of distal ligature in aortic aneurisms, it was thought right to publish this correction.—*Lancet*, March 3, 1888.

Hydrobromate of Hyoscine in Acute Mania.

In the *Lancet*, Feb. 4, 1888, Dr. George Thompson, Medical Superintendent of the Bristol Asylum, England, reports three cases of mania which were successfully treated with the hydrobromate of hyoscine. In each case the wildness or restlessness was calmed, and what is more noteworthy, the attack cut short and its recurrence rendered less frequent. The author remarks that in mania of any form the drug is the best calmative which has yet come to his notice. In some cases of general paralysis attended with dry skin and some suppression of urine, a small dose puts the patient in a much more comfortable state.

Intermittent Albuminuria.

Much has been written lately upon intermittent albuminuria. In some cases food and in others exercise seems to be the determining factor in its production. In a communication in the *Lancet*, January 7, 1888, Dr. George Johnson, who is well known for his studies upon the urine, reports two cases which illustrate the influence of food and exercise in the production of intermittent albuminuria. He states that his main object in this communication is to insist upon the practical importance of testing the urine in all cases at frequent intervals during the twenty-four hours, in order to ascertain the exciting cause of the albuminuria, and so to adopt measures to avoid or counteract it. He regards a saturated solution of prussic acid as the most delicate and trustworthy test for albumin with which he is acquainted. Any precipitate except albumin will disappear upon the application of heat below the boiling point.

He regards the term cyclical albuminuria as misleading, for it seems to imply that the abnormal condition occurs (like a tertian ague, for instance), in a regular cycle, without reference to external, ascertainable, and avoidable influences. He holds that while a treatment based upon a careful observation of the existing causes of the condition is usually successful, yet, on the other hand, it is unquestionable that however free from other symptoms of disordered health the subject of this condition may be, a frequently recurring albuminuria, if neglected, will almost invariably result, though it may be after many years, in structural degeneration of the kidneys. In one case which came under his observation, a period of thirty years intervened between the onset of this condition in connection with scarlet fever, and the fatal termination. An indiscriminate prophecy of smooth things in this class of cases may for the time be pleasing to the patient, but if this leads to the neglect of needful precautions the ultimate result will be disastrous. He denies the existence of physiological albuminuria, unless by that is meant a condition in which albuminuria exists, but with no other symptom of disordered health; in which case the greatest possible amount of albumin in the urine might in many cases be designated as physiological.

Cytisine in Migraine.

Cytisine, the name given to a very poisonous alkaloid extracted from the seeds of *cytisus laburnum*, gold rain, has the effect of narrowing the blood-vessels. The possession of this property induced Professor Kraepelin to employ it in the so-called paralytic form of migraine, and he has obtained brilliant results in two cases, which he has published in the *Neurologische Centralblatt*, No. 1. The first case was that of a young woman, 21 years old, who suffered every two or three months with violent attacks of right-sided headache. The attacks, which for the most part developed toward evening, were preceded regularly by great restlessness, a feeling of oppression, pain in the cardiac region, nausea, a redness of the right side of the face occurring in spots, and strong pulsation of the right temporal artery. After one or two hours, headache, affecting

the entire right side of the skull, began, and was accompanied with violent vomiting, anxiety, absolute loss of sleep, dread of light, and the dancing of bright specks before the eyes. The attack lasted from twelve to twenty-four hours, and was succeeded by great weakness, marked dilatation of the right pupil, and disturbance of sight of the right eye.

After various remedies had proved ineffective, Kraepelin tried at the beginning of the attack 1-22 of a grain of nitrate of cytisine by hypodermic injection. The result was surprising. In the course of half an hour the redness disappeared, and also the feeling of oppression and the pain. The same result was obtained with the greatest regularity in every one of the numerous attacks under an increase of the dose to 1-13 of a grain in the course of the following months. The drug was most active when employed at the earliest possible moment.

The second case was that of an hysterical medical student, who had suffered from his youth with violent attacks of migraine, which lasted twelve hours. Fifteen minutes after the injection of 1-22 of a grain of cytisine, the pain subsided, and in half an hour he was entirely recovered. — *Wiener med. Presse*, Feb. 5, 1888.

Preparations of Extra-uterine Pregnancies.

Mr. Lawson Tait exhibited recently, at Birmingham (*Brit. Med. Journal*, Jan. 7, 1888), a series of specimens of extra-uterine pregnancy in all stages of its development, from the earliest known case of tubal rupture, which apparently had occurred between the third and fourth week, up to a section of a cadaver at full term. The interest of these cases lay chiefly in the fact that they completely established the view as to the pathology of extra-uterine pregnancy which Mr. Tait had first published in 1873: that all extra-uterine pregnancies were due to the impregnation of the fertilized ovum on the denuded wall of the Fallopian tube; that the tube was distended up to its bursting point, which generally was from the tenth to the thirteenth week. The condition of the subsequent pregnancy depended entirely upon the point at which that rupture took place. If the rupture was into the peritoneal cavity, then death took place from hemorrhage; and twelve of the specimens shown were illustrations of this. If, on the contrary, the rupture took place into the cavity of the broad ligament, the hemorrhage was slight, and the pregnancy might go on to full term. Many of these cases, however, did not go to the full term; the fœtus died, and was thrown off by suppuration through the bladder, rectum, or into the vagina, or ended in the formation of a lithopædion. A few well recognized examples of these are to be found in almost any museum. The minority of cases went on with the child living to full term, and could be operated upon. Mr. Tait had operated seven times under such circumstances. That the danger of rupture into the peritoneum is great was shown by the case of early rupture alluded to, in which the patient was well at two o'clock in the afternoon, and was dead from hemorrhage from a small point of rupture in the tube at nine o'clock at night. In occasional instances, if rupture took place into the abdominal cavity, the placenta was separated from the tube and obtained new attachments. As one example, he showed a preparation from a patient in Nottingham— to which town Mr. Tait was summoned to perform abdominal section on account of the condition of ruptured tubal pregnancy, which had been previously recognized. He opened the abdomen, removed the fœtus, the placenta, and stump of the tube, and tied the latter. As soon as this was done the brisk hemorrhage ceased, and a part of the placenta which had become implanted on the intestine at the back of the uterus was removed, and the sites of it smeared over with solid perchloride of iron. The patient had made a perfect recovery.

Cocaine in Glaucoma.

Dr. Barrenechea reports to the *Revista medica de Chile* his experiences based upon personal observations of the use of cocaine in glaucoma. They are covered by the following propositions (*Deutsche Medizinal-Zeitung*, October 27, 1887): 1. The employment of cocaine in glaucoma produces only an anæsthesia of the conjunctiva. 2. In simple chronic glaucoma cocaine has no action. 3. The application of cocaine in chronic irritative glaucoma must be undertaken either in conjunction with pilocarpine or eserine, or some minutes before the use of these drugs. 4. If used alone in this case cocaine can give rise to an acute attack. 5. After the performance of an iridectomy in glaucoma, it is useful to employ cocaine in the combination just mentioned if pain in the ciliary region occur as a result of the irritation of the nerves. 6. Cocaine acts in glaucoma by promoting the circulation, and calling forth a greater and more permanent effect of the antiglaucomatous drugs named.

Contribution to the Etiology of Syphilitic Dactylitis.

In a paper on this subject in the *Archiv für klin. Chirurgie*, xxxvi, 1887, p. 356, Dr. Franz Eschle, of Hamburg, sums up his conclusions from his reported cases as follows:

1. Not only gummatous new formations in the medulla of the bones of the fingers and periosteum lead to the changes comprised under the name syphilitic dactylitis, but also gummata arising in the soft parts through indirect implication of the former tissues.

2. Nothing contradicts, in his cases, the assertion of Lewin that in children the osteomyelitic, in adults the periosteal form, of dactylitis predominates.

3. In syphilis (only congenital?), hereditary influences may play an important part in the predilection for a certain form of symptoms and their localization.

4. Dactylitis seems to affect especially those who are run down and badly nourished, and those who have a tendency to scrofula or tuberculosis.

5. The prognosis is bad. The obstinacy of the affection may lead to disability, with loss of the finger. It occasionally indicates so grave a form of syphilis that other complications arise which endanger the life of the patient.

Strophanthus Hispidus in Heart Disease.

Dr. Leon Rosenbusch has employed strophanthus in a number of cases, and sums up the results of his observations in the following propositions (*Berliner klin. Wochenschrift*, Feb. 13, 1888):

1. It has a marked action upon the heart, increasing the power of its systole, lengthening the systole, increasing the arterial tension and slowing the heart's action. 2. It strengthens the heart-muscle and regulates the work of the heart. 3. It acts as a diuretic in diseases of the heart, but in diseases of the kidneys its diuretic action is very slight. 4. It does not disturb digestion as other heart poisons do, especially digitalis. 5. It may be employed for weeks without giving rise to cumulative action. 6. It is best employed in the form of a pure tincture, in doses of 10 to 20 drops, three times a day. 7. It is less vigorous in its action than digitalis, and is therefore indicated especially in those cases in which digitalis has not yet been tested. 8. It maintains, especially in severe disturbances of compensation, the effect of digitalis which has been previously administered. 9. The alcoholic tincture should be employed. This contains the whole of the bitter glucoside, while the ethereal tincture may disturb digestion. 10. In stenosis of the aortic valves its action is negative, as it lengthens still more the systole; it should not be employed in this disease.

Care of the Eyes of School Children.

A very sensible decree has just been issued by the Austrian Minister of Public Instruction forbidding the use of books printed with small type in public schools, as short-sightedness is so prevalent amongst school children in Austria. The *Lancet* remarks that scientific supervision might very properly be given to school books in England, attention being especially directed to the size of the type, length of line, and spacing of letters and lines. In the works published by the Clarendon Press, the same journal thinks that no fault can be found in the respects just mentioned. The chief fault in German books is said to be their adherence to the very dazzling Old English shape of the letters, which certainly severely tries the eyes, in that it necessitates very close attention. The evil effect of this is heightened when the paper is coarse, and when the paper is read by insufficient light.

Effect of Food upon the Composition and Nutritive Activity of Mother's Milk.

Dr. St. S. Zaleski, of Dorpat, Russia, concludes a series of papers upon the effect of food on the composition and nutritive activity of mother's milk (*Berliner klin. Wochenschrift*, Jan. 30, 1888), by the following propositions:

1. Mother's milk, very rich in fat, can of itself exercise a positively injurious influence upon the well-being of the child.

2. A luxurious diet, consisting exclusively of food very rich in albumen increases considerably the quantity of fat in mother's milk, diminishes the sugar of milk, but is of less influence upon the other constituents. Alcoholic beverages have a similar effect.

3. The desirable, and for the child in special cases, indispensible composition of the milk, may be attained through suitable diet and nourishment of the mother.

4. In women the effect of food upon the composition of the milk seems to be the same as it is in animals.

5. The fat of the milk is in all probability formed, in a direct or indirect way, out of the albumen-containing the foods.

The Conditions conducive to the Earliest Possible Healing of Operation-Wounds.

In a paper read before the Surgical Section of the New York Academy of Medicine (*Med. Record*, Jan. 28, 1888, Dr. W. W. Keen stated these conditions to be as follows:

1. The use of the antiseptic method before and during the operation, and at the later dressings.
2. Thorough drainage.
3. Complete approximation both of the edges and raw surfaces.
4. The use of antiseptic dressings.
5. Securing absolute rest during the period of repair.

Brain Surgery in Dublin.

At a meeting of the Surgical Section of the Royal Academy of Medicine, in Ireland, March 2, 1888, three successful cases of trephining were reported and the discussion upon the papers was adjourned to a future night. These cases were all remarkable. Professor Thornley Stoker read particulars of a case in which a man fell from a cart while drunk. He came to the Richmond Hospital some days later, rather stupid, and with some lightly-marked paralytic symptoms. It was not easy to determine that he had not had an attack of apoplexy. The paralysis becoming more marked, Mr. Stoker trephined in the region of the fissure of Rolando—there was no fracture—and struck the margin of a blood clot. He again trephined and more fully exposed the clot, which was washed out. The area so compressed was about three inches, and the clot measured nearly an inch in depth. The patient recovered and was exhibited. Sir W. Stokes read a paper on a case of successful trephining for cerebral abscess, and exhibited his patient. The man had been struck with a poker on the left side of the mesial line of the head, about an inch anterior to the coronal suture. He was treated as an out-patient at another hospital, but ultimately applied at the Richmond, when he was admitted, several weeks having elapsed from the date of the injury. He soon presented brain symptoms, became convulsed and comatose, and it was determined to trephine. A small fracture was found under the scar; the dura mater bulging into the wound, an exploring needle was introduced to the depth of an inch and a half, and pus at last found. The dura mater was then incised, and one ounce and a half of pus was evacuated. The patient completely recovered, and is now attending to his ordinary work. The paper noted eleven other cases of abscess which had been operated upon by various surgeons, and discussed the questions involved. The third case was brought forward by Dr. C. B. Ball, of Sir Patrick Dun's Hospital, and the patient was also produced. The lad had been struck with a small knife over the squamous portion of the left temporal bone ten days before admission. The wound was healed, but he had some aphasia. Pain in the head and ear supervened, and the aphasia increased. It was determined to explore. He was trephined some weeks after the original injury. A wound was found in the dura mater corresponding to the puncture of the bone. A sinus forceps was passed in, the wound opened up, and some blood clot escaped. The patient was decidedly better, but next morning he was again aphasic. The wound was washed out, and more blood clot escaped. The aphasia almost disappeared, but two days later it returned, and the wound was again washed. After this the patient progressed favorably, and is now well. Dr. Ball pointed out the *rôle* of the brain lesion, as indicated by the various symptoms of aphasia. The group of cases was a very remarkable one, and the record of them cannot fail to influence the views of the surgeons on the subject of brain surgery—*British Med. Journal*, March 3, 1888.

Gonorrhœa in a Baby.

At a meeting of the Royal Society of Physicians in Budapest, January 21, 1888, Dr. Eröss showed a case of gonorrhœa in a boy sixteen months old. The mother complained that the child had had pain in urinating for four months. The meatus of the urethra was swollen and reddened, while from the urethra itself, seven or eight drops of a greenish-yellow pus, containing gonococci, were pressed out. No similar case is found in the chapter on diseases of the sexual organs by Prof. Bókai, in Gerhardt's Manual of Diseases of Children; but Dr. Cséri has recently reported two such cases. Under suitable treatment with injections, the discharge ceased in about a week, and the child was dismissed cured in two weeks more.—*Wiener med. Presse*, February 19, 1888.

—A family named Taylor, consisting of seven persons, and living near Sidney, Ohio, have all been taken sick as the result of eating ham which contained trichinæ. The ham was eaten raw, or but partially cooked.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

CEREBRAL LOCALIZATION.

Since the brilliant developments of the experiments of Hitzig and of Ferrier in regard to what is called cerebral localization, there has been a certain tendency to the belief that the various functions of the brain are limited to definite, if not to well ascertained portions of it, and there have been men who held the opinion that in time we might be able to map out the exact part of the brain which presides over each physiological function. This fascinating hope has attracted many students of the nervous system, and has led to some remarkable and—it must be admitted—wonderfully successful surgical operations for the relief of conditions dependent upon lesions of the brain. But there is now a sort of reaction from this sanguine opinion; and a new theory is attracting attention. This theory, which is not unlike that of Flourens, who held that any function of the brain may be performed by any portion of the cortex, consists in the belief that there are two classes of so-called "centres" in the brain: absolute centres, which justify the use of such a term as cerebral localization, and relative centres or "fields," which surround them and share their functions, while, at the same time, they pass by insensible gradation into other fields, surrounding other centres, so that there are points at which it appears probable that the function of any one of several distinct centres may be exercised. This is a view which has been defended of late especially by Exner; and in recent numbers of the *Deutsche med. Wochenschrift*, JASTROWITZ describes some of the results of modern study of the brain in order to show what appears to have been demonstrated in regard to this theory. It appears that the relation of the relative fields to the absolute centres is such that it requires a much more extensive lesion of the former to produce results like those produced by a comparatively small lesion in the absolute centres. Besides this, it seems to be a fact that the more distant the point in the relative field from the absolute centre, the greater must be the lesion to produce a corresponding effect upon the function presided over by this centre. Extirpation of an absolute brain centre results in a loss of function of the relative centre. The latter cannot replace the former.

A curious result of the study of brain function is the apparent demonstration that in most animals the left hemisphere presides more especially over the motor function, and the relative fields for motor impulses are larger than in the right hemisphere; while the right hemisphere seems to preside more especially over the function of sensation and to possess larger relative fields for this function than the left hemisphere does. But absolute centres for sensation are not found distinct from the motor centres; on the contrary the most active sensory centres coincide with the motor centres, even for single members so small as the finger. The region of the facial muscles seems to be the most sharply delimited and is separated from the zones for the muscles of the body. Upon the confines of its territory, districts are found presiding over single muscle groups. The absolute tongue centre is located in both sides of the lower section of

the anterior central gyrus and at the base of the inferior frontal gyrus; a relative field for the same is found in the supramarginal gyrus, higher up on the right side than upon the left.

The problem of mapping out the location of the seat of lesion in the various forms of aphasia is of the highest interest and importance, and is one on which the near future will probably shed a brilliant light. In this connection the unique case of Paget (*Brit. Med. Jour.*, December 10, 1887), is of the most profound interest. The patient was left-handed for everything but writing, and this fact is shown to have depended upon the location of the speech-centre in the left hemisphere, instead of—as usually happens in left-handed people—in the right. Pronounced aphasia accompanied his attacks of right hemiplegia, but the faculty of speech was normal in his attacks of left hemiplegia.

The demonstration of the existence of relative fields in connection with absolute centres in the brain, may be found to throw a new light on the formation of ideas, on the facts of re-education after lesions of the cortex, and upon many psychical functions. The ideal world of a person with partial or complete destruction of developed centres, either absolute or relative, is a different one from that of a person whose peripheral organs have been functionless from birth, or have become so from disease occurring during development. Destruction of the occipital lobes produces permanent blindness. But there is then a difference of mental life from that found in cases of congenital blindness. With destroyed centres, it is impossible to create new thought-pictures and ideas, in whose production the optical centre is a necessary factor; all connected emotions, and all movements which are their analogues or co-ordinates, all sounds and sensations which find their significance in optical images or processes, are utterly interdicted. Secondary changes, which are intimately bound up with the activities of the relative centres, must also sympathize with the deranged and extinguished functions, and the patient becomes in a certain sense demented.

THE EFFECT OF REMOVAL OF THE OVARIES.

At this time, when the ovaries of women are so frequently removed for various conditions, it becomes interesting to formulate the effect of their removal on the organism. This is especially true since it is still frequently urged, by the opponents of operative interference, that the removal of the ovaries entails very serious consequences upon the patient, such as the growth of a beard, a squeaky voice, and the loss of feminine characteristics.

Operators generally agree concerning the after history of these patients. Hegar, especially, has studied the subject. As a rule the menopause sets in at once, or after a few irregularly periodical hemorrhages. In a small percentage of cases monthly hemorrhages recur for a greater or less length of time. This is sometimes due to incomplete removal of ovarian tissue — then true menstruation continues — exceptionally to the presence of a third ovary, and usually to the presence of pelvic inflammation, vascular dilatations, blood stasis, and pelvic hyperæmia, dependent upon the pathological conditions for which the operation was done, or developing subsequently. Menstruation continues more frequently after the removal of large tumors, than after removal for other causes. This is sometimes due to incomplete removal, when a part of the ovary remains in the pedicle; sometimes to mistaken diagnosis as to the origin of the tumor, and also, more frequently, to the presence of vascular dilatations.

The uterus, tubes—when they are left—and vagina undergo the same changes, in kind, that occur after the natural menopause. The uterus sometimes undergoes very rapid and marked atrophy. The tubes are seldom left, partly because it is thought that they have an influence in the production of menstruation, and also that they are liable subsequently to become distended with fluid — hydro- or pyo-salpinx. These atropic changes are brought about by the removal of the ovaries and obliteration of neighboring vessels by ligature and thrombosis.

Many persons become stout after operation. Sexual desire usually remains, but is some-

times lost. The distinctive mental and emotional characteristics of the female are not lost. Most observers have noticed a greater frequency and intensity of the usual vasomotor disturbances, present during the natural climacteric. This is probably due to the frequent involvement of the nervous system in the morbid conditions calling for the operation, to the loss of systemic tone from previous ill-health and suffering, and also to the sudden removal of ovarian influence by extirpation.

Sterility is certain after the removal of both ovaries. Often it is present before, and a consequence of the morbid processes necessitating extirpation. The ability to have sexual intercourse is retained. The result in this respect differs from that of castration in the male, where it is usually lost. Indeed this function is frequently restored by the removal of inflamed and sensitive organs which had acted as an effectual bar. Mental depression, melancholia and suicidal tendencies, often a consequence of castration in the male, are not observed.

PROFESSIONAL CONFIDENCE.

In an editorial in the REPORTER, October 29, 1887, we expressed the opinion that it is the duty of a physician, as well as of any citizen of whatever class, to disclose to the authorities the whereabouts of a malefactor escaping from justice, although he may have learned this in his professional capacity. This opinion is sound in law, as we have assured ourselves by careful inquiry, and we believe it is equally sound from the standpoint of medical ethics, which cannot permit the shield of professional confidence to be used to protect criminals from the just reward of their crimes.

But there is a professional confidence which differs altogether from this, and which should be guarded with the greatest care. This is the confidence which a patient, unconvicted of guilt, voluntarily reposes in his or her physician. This we believe, should never be violated. No threat should be strong enough to wring from the right minded physician the secrets of his patients. Much less should a physician offer to disclose such secrets of his own free will. It is with great regret therefore that we note the fact that, according to the *Indiana Med. Journal*, March, 1888, this is exactly what a physican of Indianapolis has recently done. Being a witness in a suit for a divorce, in which the reputation of a woman was involved, he is said to have offered to reveal certain secrets which she had confided to him as her medical adviser. This offer seems to have been rejected with scorn, and the Judge who tried the case was so shocked at the conduct of the witness that he said he "would not believe on oath a physician who would reveal confidential communications received from a patient while acting in a professional capacity."

This expression of the Judge's opinion marks the sense of distrust which the conduct referred to would inspire in the mind of every decent man. Much more may physicians repudiate such conduct, and, while they may not make themselves the screens of escaping criminals, hold to the highest sense of professional honor in guarding the voluntary or involuntary confidences of their patients.

SOLVINE.

Solvine is a whitish, opalescent substance prepared by the action of sulphuric acid upon oil of almonds or castor-oil. It acquires its peculiar name because it has a remarkable solvent power upon a number of comparatively insoluble substances such as iodoform, naphthalin, naphthol, salicylic acid, cantharidin, santonin, aloin, etc. It is miscible in all proportions with glycerine, and with substances dissolved in glycerine. It forms clear mixtures with ether, chloroform, benzole, turpentine, and essential oils; and these mixtures are themselves soluble in water, if there be no great excess of any one ingredient. These facts have led to a recommendation that solvine shall be used as an excipient for a variety of medicaments intended for endermic use, instead of lard, vaseline, lanolin, and so on.

But Professor KOBERT, of Dorpat, has recently called attention to a danger which, he believes, attends the use of solvine as an external application. This danger depends

upon its ready absorption through the skin, and consists in what Kobert considers distinct toxic properties. In a paper quoted by the *Gazette Medicale*, Feb. 18, 1888, from the *Therap. Monatshefte*, Dec., 1887, Kobert states that solvine rapidly dissolves the red blood-corpuscles in a test-tube, and that when injected into the veins of warm-blooded animals, it produces serious poisoning.

These facts certainly justify the opinion expressed by Kobert that solvine should be used with prudence. Still, we believe that there are no clinical facts which warrant the theoretical fears of Kobert. How far solvine has come to be used in practice we cannot say; but there need be no timidity in employing it as a vehicle for external applications simply because its breaks up red blood-corpuscles in a test-tube, or kills frogs. Here prudence is justifiable; but not fear; and it is to be hoped that a substance which has such extraordinary powers as a solvent will not prove to be dangerous when used for the purposes for which solvine seems to be so well suited.

TRACHEOTOMY IN WHOOPING-COUGH.

After speaking, in the *Deutsche med. Wochenschrift*, Feb. 16, 1888, of the ravages of whooping-cough in Germany, which he estimates roundly at about twelve thousand deaths annually, Roser suggests the advisability of practising tracheotomy in this disease, as soon as the paroxysms of coughing have made a serious impression upon the patient's health, and when, for example, all nourishment is vomited. The justification for this suggestion lies in the fact that the coughing is very much dependent upon irritation of the larynx; and Roser believes that if the passage of air through the larynx be prevented, this irritation will cease. More than this, he thinks that if the coughing should continue after tracheotomy, it will be much less violent, since a spasmodic cough is impossible after the trachea is opened. And, finally, opening the trachea makes it comparatively easy to make local applications to the larynx, if these should be deemed advisable. In any case in which tracheotomy is performed for whooping-cough Roser recommends the use of his iodoform-tampon-canula, which we have already described in the Reporter, March 17, 1888.

The idea of adopting tracheotomy as a part of the treatment of whooping-cough will strike most American physicians as decidedly heroic; especially as the disease is by no means so dangerous here as Roser believes it to be in Germany. Still, it is not infrequently dangerous enough, and sometimes it does prove fatal; and it may be that a timely tracheotomy would save a life otherwise doomed. If so, it would be a great mistake to reject a measure which appears to have much to recommend it on purely theoretical grounds.

STATE MEDICAL SOCIETY OF ARKANSAS.

The thirteenth annual meeting of the State Medical Society of Arkansas will be held at Fort Smith, April 25–27, 1888. A "preliminary circular" announces this fact, together with the conditions of membership, and the names of the men on the various committees for the current year.

The circular, which we presume has been distributed through the State, contains the following sensible suggestions from the Secretary, Dr. L. P. Gibson:

"The members are requested to read carefully the list of committees, and to remember when their names appear there that they have not been put on the committees for ornaments, as a compliment, or to fill up the list, but solely with the object of getting as much valuable work as possible from every member of each committee.

"Chairmen are asked to correspond with every member of their respective committees, and induce them to prepare papers on the specific subjects to which they have been appointed. The foundation of the work for the meeting is almost entirely laid by the committees, and if the material furnished by them is insufficient or defective in quality, the labors of the session will be the same. The only way to have an interesting and valuable meeting is to prepare for it

beforehand, and to commence NOW. Secretaries of local Societies are requested to send to the Secretary of this Society, as soon as appointed, a list of the delegates and others who will attend from their respective counties. A full programme for the entire meeting will be sent to each member as soon as the necessary information can be obtained."

We reproduce these suggestions—not so much to call attention to the admirable method adopted to promote the success of the Arkansas State Society, as to commend it to the imitation of other State Societies. A little preliminary work of this kind could not fail to increase the activity and usefulness of any such organization.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI. Thirtieth Annual Session. 1887. 8vo, pp. xii, 159. St. Louis: Ed. E. Carreras, Printer.

One of the most interesting papers in the volume of transactions is that by Dr. H. H. Middlecamp on "The Personal Qualifications of the Surgeon," while those on the "Proper Food for Infancy and Childhood," by Dr. B. F. Hart, contains much sensible advice. A paper on "State Medicine," by Dr. J. M. Allen, and a communication by three members of the Association in regard the status and prospects of the Missouri State Board of Health are of more than local interest. As a whole, the volume is an excellent representation of the views of the medical profession in Missouri, where we find there are many firm believers in the germ-theory of disease, and some who sneer at it. The papers presented at the meeting here reported were largely devoted to surgical subjects, and not a single one discussed any of the common diseases, such as phthisis, typhoid fever, scarlet fever, etc. It is to be hoped that this indicates that these diseases are not so common in Missouri as they are in most sections of the country.

Pamphlet Notices.

ON THE MODE OF DEVELOPMENT AND COURSE OF MOLLUSCUM FIBROSUM, ETC. By R. W. TAYLOR, M.D., New York. From the *Journal of Cutaneous and Genito-Urinary Diseases*, February, 1887. 13 pp.

A FURTHER CONTRIBUTION TO THE STUDY OF MOLLUSCUM FIBROSUM; ETIOLOGY; FIBROMATOUS INFILTRATION AND ITS RELATION TO KELOID. By R. W. TAYLOR, M.D., New York. From the *Journal of Cutaneous and Genito-Urinary Diseases*, May, 1887. 11 pp.

THE TOXIC EFFECTS OF IODOFORM, CUTANEOUS AND SYSTEMIC. By R. W. TAYLOR, M.D., New York. From the *New York Medical Journal*, October 1, 1887. 20 pp.

A SECOND CLINICAL STUDY OF HEMIANOPSIA. CASES OF CHIASM-LESION. DEMONSTRATION OF HEMIOPIC PUPILLARY INACTION. By E. C. SEGUIN, M.D., New York. From the *Journal of Nervous and Mental Disease*, November-December, 1887. 19 pp.

A CLINICAL LECTURE ON TUBERCULAR MENINGITIS. By DANIEL R. BROWER, M.D., Chicago, Ill. From the *Journal of the American Medical Association*, January 7, 1888. 15 pp.

TUBERCLE OF THE TESTIS. By R. W. TAYLOR, M.D., New York. From the *American Journal of the Medical Sciences*, January, 1888. 8 pp.

PUNCTURE OF THE INTESTINE FOR TYMPANITES. By J. CHRIS. LANGE, M.D., Pittsburgh, Pa. From the *Pittsburgh Medical Review*, February, 1888. 12 pp.

ON THE USE OF THE VAGINAL TAMPON IN THE TREATMENT OF CERTAIN EFFECTS FOLLOWING PELVIC INFLAMMATIONS. By THOMAS ADDIS EMMET, M.D., New York. From the *New York Medical Journal*, February 18, 1888. 16 pp.

—Dr. Taylor's pamphlet contains an interesting study of the pathological history of molluscum fibrosum, especially in connection with its relation to acrochordon and other warty growths on the skin. The relation described is very interesting, and rests upon a careful study of a case of molluscum fibrosum, which covered a long period of years.

—Dr. Taylor's second paper on molluscum fibrosum contains a continuation of the study which formed the object of the pamphlet last noticed. The author here considers more especially the relation of molluscum fibrosum to keloid, and describes two cases under his own observation in which the appearance of the former seems to be attributable to traumatism, thus corresponding to the usual history of keloid.

—Dr. Taylor has studied the local and systemic effects of iodoform used as an antiseptic, and he presents the results of this study in a very practical paper. He finds that there are too many reports of mild or severe iodoform poisoning to permit an explanation of them on the ground of idiosyncrasy. He advises surgeons not to use iodoform unsparingly, not to rub it into fresh wounds, not to renew it too often, not to combine its use with the employment of other antiseptics, and to use it with caution on patients who are quite young or quite old, or who are anemic, neurotic, or suffering with a weak heart or with Bright's disease.

—Dr. Seguin's paper is a very finished study of the interesting subject of hemianopsia, as illustrated by three cases, the clinical history and rational signs of which seem to justify his opinion that the defect was due to a lesion situated at the optic chiasm. The cases are admirably described, and the written description is supplemented by excellent wood-cuts. The method of investigating these curious cases, as given by Dr. Seguin, is calculated to be of especial service to students of diseases of the eye and of nervous diseases.

—Dr. Brower's paper describes the history and pathological lesions of tubercular meningitis very clearly, and especially well the changes which are sometimes observed at the inner margin of the iris. The last are illustrated with three diagramatic

wood-cuts. Dr. Brower expresses the opinion that inunctions of iodoform upon the shaved scalp are the best means of treatment yet discovered, and prudently suggests that careful management of children with a tendency to tubercle may go far toward preventing the development of this dangerous disease.

—Dr. Taylor gives the clinical history and the macroscopical and microscopical appearances found in two cases in which he removed both testes for supposed tuberculosis. In both the diagnosis seems to have been correct, although no mention is made of finding tubercle bacilli in the organs removed from one of the patients, while such a discovery is distinctly asserted of the other. The paper is illustrated with well executed wood-cuts.

—Dr. Lange takes the somewhat unusual position that puncture of the intestine for the liberation of gas, which is producing great distension of the abdomen and consequent pressure upon the contents of the thorax, is a justifiable and useful operation. Most surgeons have a great fear that such a procedure may cause peritonitis, and that its dangers overbalance its benefits. Dr. Lange holds a diametrically opposite opinion, and supports this opinion by an interesting argument, and by citing eight cases in which he punctured the intestine for tympanites with excellent results. Two of his patients died, it is true; but there seems no reason to attribute their death to the operation, while six of his patients recovered. For the details of these cases and the manner of performing the operation we must refer our readers to Dr. Lange's valuable paper.

—The first part of Dr. Emmet's scholarly paper is occupied with a statement of the advantages to be derived, in suitable cases, from the use of hot-water injections for the relief of inflammation of the pelvic viscera of women. He then considers the use of the vaginal tampon, which does great good in certain cases of inflammation with relaxation of the veins of the uterus and its appendages. The material preferred by Dr. Emmet is clean cotton—not absorbent cotton. He choses this rather than wool, which is now in great favor, and which appears in the hands of other surgeons to have answered the purpose admirably.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*The Climatologist* is the name of a new periodical "conducted" by William C. Chase, and published in Washington, D. C. It is a quarterly journal, large octavo size; price, 50 cents a year. The first number contains 64 pages. The matter is interesting, though much of it is far from fresh. The paper and printing are poor, and there are a number of evidences of careless proof-reading. It is to be regretted, also, that its first number is disfigured by advertisements inserted in the middle of the reading pages, and inseparable from a part of its scientific contents. A journal which appeals to the sympathy of older ones should not begin with a practice which is regretted by all, and repudiated by the best.

—The *Dental Cosmos* for March, 1888, contains 80 octavo pages. This increase in the size of the *Cosmos* will be permanent, and will materially enhance the value of a periodical which always enjoys an enviable reputation.

The Prophylactic is the name under which the *Canada Health Journal* now appears. The first number of the new series is dated February, 1888. It contains 40 octavo pages of interesting matter relating to hygiene. It is published in New York by M. B. Playter & Co., monthly, at $1.75 a year.

—"Dr. Griffith Gramtry," by Julian Hawthorne, in *The Cosmopolitan* for March, is a dramatic story, hinging upon the hypnotic power that an unscrupulous man exerted upon a couple, just married, and spending the honeymoon on a picturesque portion of the Irish coast.

Correspondence.

To what Class of Fungi does the Diphtheritic Belong?

Editor Med. and Surg. Reporter:

Sir:—In looking up the literature of fungi, my attention was called to some quotations from the works of Prof. Hurtig (*Nature*, January 12 and 19, 1888), on the *dry-rot* of timber, which he shows proceeds from the growth of the *merulius lacrymans*, and from the *polyporus vapriosus*. The surface of the fallen timber or joist is covered with a whiteish or colored membrane made up of a mat of fine threads, the roots or *hyphe*, penetrating the pores of the wood deeply, disintegrating it and causing it to fall to pieces. When the nutriment or moisture under it is exhausted, it sends out long threads to other wood where moisture is more abundant.

The *merulius* grows on dead timber; the *polyporus* on living, its mycelium appearing in long, white ribbons, or thick, leathery membranes of a yellow color. Its roots extend deeply into the tissue of the wood, causing softening and decay. It can be transplanted, but for some time the spores could not be made to germinate. It was found that the *merulius* required an alkali, which, in damp places, is in the form of ammonia, from decomposition. It is not stated how the *polyporus* is produced from spores. In making some microscopic examinations of both forms of fungi, I was struck with the resemblance of the mycelium of the *polyporus vapriosus* to the diphtheritic membrane, and also to the similarity of its transference and manner of reproduction. Diphtheritic membrane can be transplanted. I have a distinct recollection of a patch that appeared on a small bruise on my finger, and the difficulty I

had in removing it from a large, blistered surface. We have been classifying it as a *schizomycetis*, when in fact, it is a fungus of a higher order: a *hyphomycetis*. We have been looking for the bacteria and micrococci, which produced the disease, and describing the membrane as an exudation, instead of treating it as a fungus that grows on the surface and has its roots penetrating the tissues. We have two or three diseases evidently of the same class, but milder: the aphthæ or thrush of children, which is recognized as a mould—*oidium albicans*—whose roots penetrate the mucus membrane, and which is capable of being transplanted and being propagated by spores. We have also favus and herpes (ringworm?) which are fungus diseases.

There is no diphtheria now in my vicinity, so that at present I have no means of making any microscopic examination. Will some one who has the opportunity, do so? For, if the fact can be established, it will have much to do with our treatment of this formidable disease. A fungus is planted in the throat; it spreads by fibrillations; its roots enter into the tissues below, disintegrating them and generating a poison, which is taken up by the circulation; and then a local disease becomes constitutional. The softened tissue forms a soil for the development of bacteria and putrefaction, and entire destruction takes place. Otherwise, the membrane extends farther into the air-passages, and so fills them up that death takes place from suffocation. Diphtheria transplanted to the surface produces severe irritation and a troublesome sore, which is not cured until the membrane is destroyed.

P. J. Farnsworth, M. D.

Clinton, Iowa, Feb. 22, 1888.

Pamphlets Noticed.

Editor Medical and Surg. Reporter:

Sir:—The Reporter often contains notices of pamphlets which seem to be very valuable. Of whom may they be procured? Of the general medical book trade?

Yours truly,

Drs. Worthington & Wilson.

Merrill, Wis., March 6, 1888.

[One who wishes to obtain a pamphlet noticed in the Reporter may address us for it, or the author of the pamphlet, or the journal in which it originally appeared. Either course will usually secure a copy without cost, except postage, which ought always to be sent.—Editor.]

Notes and Comments.

Bichloride of Mercury Internally in Circum-uterine Inflammations.

In the *New York Med. Journal*, January 28, 1888, Dr. H. N. Vineberg has a communication upon the internal administration of bichloride of mercury as an adjunct to the local treatment of circum-uterine inflammations. He reports several cases in which he has employed this drug, which he gives with compound tincture of gentian and water, in the strength of one grain to three ounces of the mixture; dose, a teaspoonful three times a day, after meals.

The patients, he says, took the mixture readily, and, with only one or two exceptions, no complaint was made on the score of its taste. Some of the patients took the remedy in the dose stated continuously for four or five weeks without the slightest evidence of mercurialism. It was usually then omitted for a week, more for precaution's sake than on account of any untoward effect of the drug. On the contrary, the appetite of the patients while they were taking it usually improved, as did also their digestive functions. When anæmia was present, the bichloride was combined either with tincture of chloride of iron or with reduced iron in the form of a pill. In some cases he gave as much as one-sixteenth of a grain—a dose which the patients seemed to bear as well as the smaller ones. From his observations, which have just been referred to, he draws the following conclusions, which he thinks are warranted:

1. The use of bichloride of mercury internally forms a valuable aid to the local treatment of circum-uterine inflammations.

2. In the doses necessary for its resolvent effect the drug may be given for several weeks without any untoward constitutional manifestations.

3. In some cases, where the inflammatory products are deeply situated within the pelvis, the internal use of the drug seems to be more efficacious than the most approved local treatment.

4. A short course of the drug often serves as an important means for the differential diagnosis of the various obscure conditions which give rise to pelvic pain.

Communication of Tuberculosis by Ritual Circumcision.

Mr. F. S. Eve, assistant surgeon to the London Hospital, in a communication on the above subject to the *Lancet*, January 28, 1888, reports the case of a Jewish child,

five months old, who was admitted into the hospital on August 23, 1887, with a large globular, fluctuating swelling in each groin. The skin over these swellings was red and thinned. On the under surface of the penis, at the site of the frænum, was a small superficial sore. The abscesses were opened, and a quantity of pus, containing some masses of caseous material, was evacuated. Their walls were then scraped. The child's condition improved, and in fourteen days he left the hospital, with a sinus in each groin, discharging only a small amount of pus.

The mother of the child stated that it had been circumcised on the eighth day, and the wound appeared to heal properly. Six weeks afterwards she noticed a small swelling in each groin, and it was then found that the circumcision wound had either broken out again or had not healed. Caseous material taken from the abscesses by Mr. Eve produced intense general tuberculosis in a Guinea-pig which was inoculated with it.

Oil of Sandal Wood for Gonorrhœa.

Dr. M. H. Linhart, in *Wiener med. Presse*, Nos. 29–34, 1887, strongly recommends the use of oleum santali in the treatment of gonorrhœa. He gives the oil in capsules containing each three drops; and orders these capsules to be taken each morning and evening—that is, eighteen drops each day. When the discharge does not diminish materially in ten days, he increases the quantity to be taken to twenty-four, and, in rare cases, to thirty drops a day.

According to Linhart, sandal-wood oil can be given in any stage of gonorrhœa, and is not contra-indicated by any of its complications. In his experience the average time required for a cure under this treatment was four weeks; by the method of injections he has found it to be six weeks.

The use of sandal-wood oil for gonorrhœa is not a therapeutic novelty, and it is certainly not an infallible means of effecting a cure; but it is a good thing to know what it may do, and to give it a trial in the treatment of this stubborn disorder.

Application for Warts.

E. Vidal recommends the following solution:

℞ Acidi salicylici.....1 part
Alcoholis (90 %).....1 "
Etheris sulph.....2½ "
Collodii.....5 "
M. Sig.—Paint the warts daily with the solution.

Oleate of Copper for Ringworm.

The *New Orleans Med. and Surg. Journal*, March, 1888, states that Dr. Blanc, of that city, has recently treated twenty-seven cases of ringworm of the scalp with oleate of copper. The following is the formula:

Oleate of copper.....½ drachm.
Vaseline (or lanoline).....1 ounce.
Mix.

The child's head was first washed thoroughly with soft soap and warm water, after the hair had been cut as close as possible. The head is then well dried, and the ointment rubbed in the scalp, over and beyond the diseased spots, and allowed to remain on. The head is scrubbed only once a day, but the ointment is applied night and morning. Chrysarobin was also tried, but abandoned. Dr. Blanc found the oleate of copper especially useful in cases of tinea complicated with "kerion" (a humid, boggy, honeycombed condition).

The average duration of treatment was four months and four days—the shortest time being seventy-four days, and the longest one hundred and sixty-six days. All the cases were cured. The disease was communicated to the boys by two pet cats who were affected with it. Epilation was not practiced in any of the cases.

This result is an exceedingly happy one, and Dr. Blanc deserves to be congratulated upon it. It is to be regretted, however, that no mention is made of the length of time the boys were kept under observation after their apparent complete recovery. The disease is so treacherous that no case should be finally dismissed as positively cured which has not been found to be free from all evidence of relapse for at least two months.

For Rheumatism.

L. A. Smith sends to the *Chemist and Druggist*, Nov. 26, 1887, a sample of a specific for rheumatism, to which many marvellous cures are attributed,—some, indeed, with one application. The "specific" is an oily fluid, of a pale straw color and slightly terebinthinate odor. A preparation similar to it is afforded by the following formula:

Oil of anise.....f℥ij
Oil of turpentine.....f℥iij
Oil of camphor (natural).....f℥ij
Olive oil to.....f℥x
Mix in the order given.

The statements regarding the miraculous influences of such preparations as this must always be taken *cum grano salis*. The heating nature of the mixture no doubt affords temporary relief, which is enhanced by faith, —and there is a great deal in the rubbing.

Professional Confidence.

The following somewhat unusual action of a medical man in reference to secrets of the medical "confessional" is narrated in the *India Medical Gazette*. In the court of Madras, A prosecuted B under the Penal Code, for adultery with A's wife. The fact was sworn to by A's wife in court. Dr. C., a surgeon in the Madras medical service, sent word to the counsel for the defense that he could give testimony which would help the accused. On being summoned, he narrated facts made known to him in conversation with Mrs. A., regarding a previous adultery. This evidence was ruled out, as Mrs. A. was present to declare what she did say, and she totally repudiated the conversation. The judge, moreover, censured the doctor for volunteering to give away the secrets reposed in him professionally, but said that if he were summoned involuntarily he would have been obliged to testify to facts thus learned. If the latter is the case, and the law had no respect for professional secrecy when it summons a witness to its own aid, it is a delicate question how far, supposing the doctor to have been honest in his testimony, he was obliged to sit still and see an innocent man suffer injustice from want of that evidence which under slightly different circumstances the law has a right to extort.—*Boston Med. and Surg. Journal*, March 8, 1888.

Rumination in the Human Subject.

Two cases of this rare abnormality are recorded by Dr. Axel Johannessen in the *Zeitschrift für klin. Med.* 1887, Bd. 12, S. 321. In the first case, the patient, a man 25 years old, had suffered in his fifteenth or sixteenth year, from some cerebral affection, diplopia, giddiness, tinnitus aurium, head ache, and stomach ache being present. After these, came disturbances of some organs of sense, convergent squint of the right eye, deafness of both sides. Later on, deposits of chalk were observed in the tympanum, and loss of smell on the left side. Moreover, all kinds of food after they had been chewed and swallowed, returned in from half an hour to two hours, and were again masticated and swallowed, with pleasure. The regurgitated morsels were not ejected until within the last six months, since which time a sour, bad smelling fluid has accompanied them. Since then, also the appetite has failed, and the patient has become thinner. In the second case, the rumination appears to have come on after the eruption of some teeth, which was accompanied with febrile symptoms. The patient was a healthy boy, 10 years of age, born of healthy parents. The boy is now a man of 28, but the rumination still continues. It can neither be set up, nor kept back by any voluntary effort, and in this case also it is associated with pleasurable sensations. Before the regurgitation begins he experiences a feeling of pressure about the level of the larynx. This, however, disappears when the regurgitation has taken place.—*Medical Press and Circular*, Feb. 1, 1888.

Large Nævus in an Unusual Location.

Dr. A. McShane records the following interesting case in the *New Orleans Medical and Surgical Journal*, December, 1887: The patient was a young white man, aged 20, in good physical condition. Five years ago a friend, while looking at his back teeth, observed a large swelling on the right side of the soft palate. In October, 1887, there was a large purplish bulging in that locality, involving the pillars of the fauces and the uvula, which is three-fourths of an inch long, and very thick. Immediately to the right of the uvula is a slightly elongated, blackish mass, projecting downward, which consists of distended veins. All over the surface of the swelling numerous dilated blood-vessels are seen, giving a mottled, purplish aspect to the tumor. The swelling is soft. The patient does not know how long he has had it; he himself first noticed it five years ago, and it was as large then as it is now. The swelling is a large nævus, occurring on the mucous membrane of the soft palate and fauces. It causes no inconvenience in swallowing or speaking, but swells a little when he gets a cold.

The Propriety of Operating for Fistula in Ano when Phthisis Exists.

Dr. Joseph M. Mathews, Professor of Surgery in the Kentucky School of Medicine, states his opinions with reference to the propriety of operating for fistula in ano when phthisis exists, in the following propositions, (*Atlanta Med. and Surg. Journal*, February, 1888):

1. In incipient phthisis the operation is always justifiable, other things being equal.

2. In the rapid, progressive fistula, an operation should be done to save tissue and prevent serious consequences.

3. If great cough exists it should militate against the operation.

4. If it can be determined that the sinus is single and the discharge, inconvenience and pain not great, advise against the operation.

So-called Idiopathic Dilatation of the Colon.

At a meeting of the Clinical Society, of London, Jan. 27, 1888, Dr. Angel Money and Mr. S. Paget read a paper on a case of so-called idiopathic dilatation of the colon. The patient was a man 55 years old, an habitual drunkard who suffered from enormous distention of the colon, with dispnœa and bronchitis. The girth of the abdomen was over 60 inches, and the measure from the ensiform cartilage to the pubes 26 inches. There was albuminuria. He was first treated by Mr. Paget at St. Thomas's Home by repeated punctures. These gave great relief; he improved so much that he refused further treatment, and returned to his drunken habits. He was admitted into University College Hospital a week later, under Dr. Angel Money, with the same enormous distention, lividity, and dyspnœa. He was much relieved by the use of the long rectal tube, but sank and died a week after admission. At the necropsy all the signs of habitual drunkenness were found, including typical "hobnail" liver. There was enormous distention of the colon, principally of the sigmoid flexure, which formed two huge sacs extending right across the abdominal cavity. There was no organic stricture. Dr. Money is of opinion that a twist of the sigmoid flexure or a spasmodic stricture may have been present; or else that some morbid state of the blood, or the mere presence of an excess of gas, may have started the disease. The bowel was hypertrophied as well as dilated.

The omentum was in a state of chronic cirrhosis, but was not adherent, nor displaced into a hernia. The meso-colon was not unnaturally long.—*Medical Press and Circular*, Feb. 1, 1888.

Court-Bibles and Disease Germs.

Dr. Drescher, State Analyst of New Jersey, was a witness in a case, tried before a Justice of Newark, N. J., on March 2, and before giving testimony in the case, he merely made a pretence of touching his lips to the time-stained volume. The counsel for the accused observed the doctor's omission, and, after arguing the case in every way that his ingenuity could suggest, he raised the point that Dr. Drescher's oath in the case was invalid, because he intentionally avoided kissing the book.

A tilt between the lawyers followed, and Dr. Drescher admitted that he did not kiss the book, but said the omission was prompted by sanitary motives and not by irreverence. He said he was afraid to touch his lips to an article that might cause disease. "So many different persons have kissed that book that I do not think it safe to touch my lips to it."

Justice Otto said the case must be reopened, and that the doctor must be sworn properly. Dr. Drescher then took the Bible, gave it a sounding smack, and then vigorously rubbed his lips with his handkerchief to remove any bacterial germs which might have been taken up in the process of osculation.

The Language of Twins.

Dr. W. H. S. Crabb writes to the *St. Louis Med. and Surg. Journal*, Jan., 1888, that he has frequently observed that twin children, if both live and are kept together, do not learn to speak and use words that can be understood as readily as other children, but on the contrary they almost always understand each other. He is satisfied that there is really something more than a mere coincidence in it. He says he is acquainted with a couple of twin boys, seven years old, who can understand each other, although it is impossible for their parents or any other person to understand one word they say. He also knows of twin girls, sixteen years old, who can talk to each other, but to another person their language would convey as little meaning as the ancient Hebrew would to a person who had never learned that language. The young ladies mentioned can use a great many words common to the English language in talking with other people, but in conversation with each other they use a language of their own invention and peculiar to themselves. In each of the cases referred to he recommended the separation of the children so that necessity, the mother of invention, would cause them to use the language of the persons with whom they come in contact.

Prescriptions for Phthisis.

The Paris correspondent of the *Medical Press and Circular*, February 1, 1888, states that the following prescriptions have been much used by Paris physicians:

℞ Potass. iodidi ..... ℥iss
Sodii arseniat. ..... gr. j
Syrupi aurantii ..... f℥ij
Aquæ ..... q. s. ad f℥x
M. S.—Tablespoonful every morning.

℞ Creasoti ..... ♏j
Iodoformi ..... gr. ss
Ext. opii ..... gr. ½
M. ft. pil. No. j. S.—To be taken morning, noon and night.

Christian Science.

Dr. Edward J. Doering writes to the *Chicago Tribune*, January 17, 1888, that the recent death in Chicago of a patient of the so-called Christian scientists was by no means the first occurrence of this kind. He states that he, as well as many other physicians, has signed death certificates for many deluded victims of "Christian Science." He adds: "We do so in order to save the family and friends of the deceased the mortification of a Coroner's inquest, when we are satisfied, of course, that nothing of a criminal nature—in a legal sense—has occurred. If these Christian healers could only be sentenced to the work-house at hard labor for the term of one year, and their patients be sent for a similar period of time to an institute for feeble-minded persons, a large number of cranks could be restored to common sense and many an untimely death be averted.

Tetanus after Hypodermic Injection.

The *Lancet*, January 28, 1888, states that a child six years old suffering from miliary fever was treated first with quinine administered in pilules and by inunction, and then by a subcutaneous injection. One month later the fever had disappeared, but the child complained of pains in the left arm and at the point of injection; trismus supervened in three days, tetanus developed, and death occurred on the sixth day. If this was really a case of traumatic tetanus, the period of incubation was rather longer than the usual seven to fourteen days.

Adonis Vernalis.

This drug was first recommended by Meud and Cullen, in England, as a diuretic and purgative, and subsequently by G. Sée, Laborde and Le Gris. It is used in place of digitalis in heart diseases and dropsy, but its action is greater as a diuretic than as a heart stimulant. Nausea, vomiting and diarrhœa are easily produced by it, but it has no cumulative action. It may be given in the form of the infusion, of a strength of two to four per cent., in doses of a tablespoonful every two or three hours.

Congenital Torticollis.

Dr. John D. S. Davis, from a study of this affection (*N. Y. Med. Journal*, February 4, 1888), concludes:

1. That it is rare and doubtful if ever congenital torticollis is produced through the act of delivery, resulting from faulty application of the forceps, or from pulling out the trunk before the head is extracted; but that the cause may often be found in the low vitality of the fœtus of scrofulous parentage.

2. The complete resection of all the contracted (contractured) tissues is necessary before attempting to restore the head to its normal position.

3. That, after complete section of the tissues, the head should be placed immediately in the normal position, and retained there for ten or fifteen days.

Improved Method of Making Suppositories.

Some time ago Mr. Adolph Vomacka, the accomplished pharmacist and editor of the *Rundschau* (Prag), contributed to his journal a new and improved method of making suppositories of those medicines which do not easily or thoroughly incorporate with cacao butter under the old process (such, for instance, as green extracts, iodoform, etc.) Very recently M. Leboutte, a Belgian pharmacist, contributed the same, as original, to the *Bulletin* of the Pharmaceutical Society of Brussels. It is as follows: Reduce a sufficiency of cacao butter to a powder in a mortar, mix the medicinal agent, and add a small quantity of soap. When the whole is reduced to a powder, add a small quantity of water and work up the mass as though pills were to be made. Divide and make into cones in the usual manner.—*National Druggist*, Feb. 15, 1888.

Terpinol Pills.

Terpinol, the new antiseptic derivative of turpentine, is coming rapidly into practice not only in Europe but in America. Benzoate of ammonium is one of the remedies with which it is combined in prescriptions, especially in pill form. Considerable difficulty was at first experienced in making the latter, and the following, sent by O. Kaspar to the *Chemist and Druggist*, is the best solution of the difficulty we have yet seen:

Take of

Terpinol	10 parts.
Ammonium benzoate	10 parts.
Ceræ flav. ros	10 parts.
Pulvis constituens	10 parts.
Glycerin, tragacanth	q. s.

The *pulvis constituens*, constituting the fourth ingredient, consists of equal parts of gum arabic, sugar and powdered althea. The only difficulty about this formula is that it makes rather a large pill.—*National Druggist*, Feb. 15, 1888.

Detection of Concealed Insanity.

Dr. Allan McLane Hamilton, in a communication to the *New York Med. Journal*, upon the detection of concealed insanity by the use of nitrous oxide gas, says that its use for that purpose was suggested accidentally to him by a case of insanity with concealed delusions. He has invariably found, when the patients studiously avoided betraying their mental weakness from fear of asylum detention or commitment, or when there was no such restraint—that the simple suggestion of the suspected condition, or the mere establishment of the first grade of intoxication—would result in their giving prompt expression to not only delusions, but sometimes hallucinations. The particular form of monomania would be intensified, and even new applications of the dominant false idea would be made.

Physiological and toxic Action of Cocaine.

Le Concours Médical states that M. Laffont has communicated to the Academy of Sciences and the Academy of Medicine some conclusions relative to the following physiological effects produced by cocaine:

1. General peripheral analgesia, only involving the extremities of the peripheral nerves.

2. Preservation of the excitability of the nervous trunk, and even a notable increase in this excitability.

3. Persistence of the reflexes in spite of peripheral analgesia.
